there has been a falling off in the number of persons employed to the extent of 1581. There were seventy-four fatal accidents during the year, fifty-five of them in the coal mines, seventeen at the ironstone, and two in the metalliferous mines. In the previous year there were the same number of fatal accidents, when, however, thirteen occurred in the coal mines, ten at the ironstone, and one in the metalliferous mines. The death-rate was higher in the aggregate than in the preceding year, there having been eighty-three lives lost in the coal mines, seventeen at the ironstone, and two at the metalliferous mines. This increase was due to the explosion at the Elenore pit last December, and if the loss of life from that accident were deducted the death-rate would be the lowest in any year during the continuance of the present Acts.

POISONING BY PHOSPHORUS.

An inquest was held last week in Newcastle on the body of a young married woman, who, after a quarrel, purchased eight boxes of matches and swallowed an infusion she had made of the heads. She never complained for about four days, when, her symptoms becoming acute, Mr. Foggin was called in, and she confessed to the act, surviving nearly seven days.

THE NOTIFICATION OF MEASLES.

At a meeting of the Newcastle Sanitary Committee held last week, it was stated that a serious epidemic of measles at present existed in the city, and after some discussion the following motion was carried by ten votes to five: "That the Council at its next meeting be requested to take the necessary steps for the notification of measles similar to the notification of other infectious diseases."

DEATH OF DR. LUCIUS HOLLAND OF NEWCASTLE.

I regret to announce that another active and well-known practitioner in this city, Dr. Lucius Holland, has fallen out of the ranks. Dr. Holland died at his residence in this city on Tuesday morning last. For a short time he had suffered from sore throat, and had been confined to his house, but within the last few days before his death the affection assumed a very grave and ulcerated appearance, causing his strength to give way rapidly. He was attended by Drs. Scott and Barkus. Dr. Holland, who had nearly reached his forty-fourth year, was born at St. Ives, and was the son of a Presbyterian minister there, he himself being originally destined to enter the same ministry; and he studied at the Theological College of English Presbyterians in London, under the late Dr. Lorimer. Some scruples precluded Dr. Holland from following theology, and he took to medicine, and finished a very distinguished course as a student at Aberdeen, where he graduated, and ultimately became an M.D. He came to Newcastle about twelve or thirteen years ago, and commenced private practice. He was one of the physicians to the Newcastle Infirmary, and had charge of the aural department in that institution, where he also lectured on Aural Surgery. Dr. Holland has left a wife and two young children to mourn their loss.

Newcastle-on-Tyne, July 26th.

DUBLIN.

(*From our own Correspondent.*)

THE DUAL SCHEME BETWEEN THE APOTHECARIES' HALL AND THE COLLEGE OF SURGEONS.

The dual scheme proposed by Sir Charles A. [illegible] of a combination between the Royal College of Surgeons with the Apothecaries' Hall, as well as with the College of Physicians, has become an accomplished fact. The College of Surgeons will appoint two examiners in [illegible], two in Ophthalmic Surgery, two in Anatomy, two in Physiology, one examiner in Midwifery, one in Chemistry, and one in Physics. The Apothecaries' Hall will appoint two examiners in Medicine, two in Pharmacy, two in Materia Medica, two in Forensic Medicine, and Hygiene, one examiner in Midwifery, one in Chemistry, and one in Physics. To qualify as examiners in Medicine and Surgery candidates for those offices must be clinical physicians and surgeons of five years' standing, while the examiners in Midwifery are required to be ex-masters or ex-assistants of Lying-in Hospitals. Each body pays its own examiners and charges its own fee for diploma. It is probable that the Apothecaries' Hall will charge £6 for their diploma. I am in a position to state that the Council of the Royal College of Surgeons have resolved to confer the Honorary Fellowship of their College upon the following gentlemen—viz., Sir G. Macleod (of Scotland), Messrs. C. Macnamara, Heath, and Erichsen (of London).

BRITISH MEDICAL ASSOCIATION: DUBLIN MEETING.

The meeting to be held next week in Dublin is regarded with considerable interest; and as the place is so central and convenient to a large number of the members of the Association, it is expected that it will be well attended. The President-elect will be Dr. Banks, Regius Professor of Physic in the University of Dublin; and there will be an address in Medicine given by Dr. Gairdner; one in Surgery, by Mr. Edward Hamilton; and in Public Medicine, by Rev. S. Haughton. There will be eight sections and two sub-sections—viz., Medicine, Surgery, Obstetric Medicine, Therapeutics and Pharmacology, Pathology, Public Medicine, Psychology, and Ophthalmology; the sub-sections being Otology, Laryngology, and Rhinology. The meetings will take place and the addresses will be delivered in Trinity College. In the Medical Section there will be a special discussion on the different kinds of Aphasia, introduced by Dr. Charlton Bastian. In the Section of Surgery there will be a discussion on the Radical Cure of Hernia. In Obstetric Medicine there will be two subjects for discussion—viz., on the Prevention of Puerperal Fever, and on the Management of Anterior and Posterior Displacements of the Uterus. The special subject for debate in the Section of Therapeutics and Pharmacology will be the Therapeutics of the Uric Acid Diathesis, which will be introduced by Dr. Burney Yeo; in the Section of Pathology, the Pathology of Empyema and the Etiology of Chlorosis; while the subjects for discussion in the Section of Public Medicine include the Influence of Modern Preventive Measures on the Prevalence of Infective Diseases; and How to deal with the Insanitary Property now occupied by Artisans and Labourers. The latter will be introduced by Sir Charles Cameron, medical officer of health for Dublin. The other subjects for discussion will be Nervous Disorders following the use of Anæsthetics, and on Private Treatment *versus* Asylum Treatment, in the Section of Psychology; the Etiology and Treatment of Convergent Concomitant Strabismus, in the Section of Ophthalmology; on Tinnitus Aurium in the Section of Otology; and on Phthisis of the Larynx, and the Reflex Neuroses of the Naso-pharynx, in the Sub-section of Laryngology and Rhinology. Saturday will be, as usual, the day selected for excursions to various places of interest.

DUBLIN MAIN DRAINAGE.

At a meeting of the Corporation of Dublin last Monday, it was moved that a committee should be appointed to inquire into the advisability of dealing with the main drainage question by means of intercepting sewers only, in connexion with some system of purification. Also that the Council sanction an expenditure of a sum of money, not to exceed £200, for the purpose of securing every information as to the working of existing intercepting and purification schemes. It is thought the proposed work can be carried out for £150,000.

OUTBREAK OF MEASLES IN DUBLIN.

This disease being still very prevalent in Dublin, Sir C. Cameron, medical officer of health, in a recent communication, urges the working classes to remove their children to the city hospitals, and also to apply for disinfectants to the authorities.

DUBLIN HOSPITALS BILL.

This Bill, which has been introduced by some of the Nationalist members, has, it is believed, little chance of becoming law. As a contemporary points out, it is intended as an attack on the Richmond Hospital, which has done good work, and I may add it is proposed to utilise the grant of £8000 which the Richmond Hospital at present receives to augment the funds of the Mater Misericordiæ Hospital. The closing of the Lock Hospital—a most valuable institution,—as contemplated by the Bill, and the injury it would inflict, if it became law, on other institutions, will no doubt cause it to be strongly opposed. As the Bill most probably will be blocked, it is not necessary for the present to refer at any considerable length to the subject.

Dublin, July 28th.

ROYAL COLLEGE OF PHYSICIANS.

THE ordinary Comitia of the College of Physicians was held on the 28th inst., Sir W. Jenner, Bart., President, in the chair. The question whether a medical officer to an institution, who had to dispense medicine in that capacity, could be eligible for the Membership of the College was discussed; but no decision was arrived at.

A communication was read from the Home Secretary, conveying Her Majesty's thanks to the College for their address.

A communication was read from the General Medical Council enumerating the titles registrable under the Act of 1886, and it was announced that the list had been amended to include the College licence.

A letter from the Councils of King's College and University College, enclosing a copy of their draft petition to the Crown, was read, and referred to the Committee of Delegates.

On the recommendation of the Council the Baly medal was awarded to Dr. Ferrier.

The reports of the Finance and Library Committees and of the Curators of the Museum were read and adopted.

A report from the Committee of Management, containing recommendations as to the examination in Public Health and other matters relating to the regulations of the Conjoint Board, was read, and after some discussion adopted

The report of the Leprosy Committee was read and adopted, and it was directed to be sent to the Colonial Secretary. The report stated that if leprosy contained elements of contagion, it was not more to be dreaded than syphilis, but that it was desirable that the subject should be again investigated; and it was recommended that the Government should undertake such investigation as the College should direct.

The following Fellows were elected to the undermentioned offices:—Censors: Alfred Baring Garrod, M.D.; John Syer Bristowe, M.D.; James Andrew, M.D.; Peter Wallwork Latham, M.D. Treasurer: Sir Dyce Duckworth, M.D. Registrar: Sir Henry Pitman, M.D. Harveian Librarian: William Munk, M.D. Assistant Registrar: Edward Liveing, M.D. Curators of the Museum: William Wegg, M.D.; Lionel Smith Beale, M.B.; Henry Charlton Bastian, M.D.; John Curnow, M.D.

GUY'S HOSPITAL.—The library of this hospital will be closed on Saturday, the 6th of August, at 3 P.M., and reopened on Monday, August 29th, at 9.30 A.M

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the Primary Examination on July 7th:—

Fullard, John, Queen's College, Birmingham.
Johnson, Philip, St. Bartholomew's Hospital.
Hildyard, Nathaniel, University College.
Tyson, Edward, St. Bartholomew's Hospital.

The following gentlemen passed their Examination in the Science and Practice of Surgery on July 14th:—

Brennan, Joseph Richard Mary, Owens College, Manchester.
Haviland, Frank Papillon, St. George's Hospital.
How, George Bradley, Owens College, Manchester.
Samman, Charles Thomas, London Hospital.

The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on July 20th:—

Baldwin, Henry Clifford, Lockwood, Huddersfield.
Brennan, Joseph Richard Mary, Congleton, Cheshire.
Bryett, Lewis Thomas Fraser, Girdler's-road, West Kensington.
Caley, William Birch, Stanley-road, Liverpool.
Cooper, Henry C. Evans, Myrtle Cottage, Southall, Middlesex.
Greeves, Thomas Neville, South-hill Park, Hampstead.
Powell, Herbert Edward, Battersea-park-road, S.W.
Watkins, Frank Augustus, Stowe Park, Newport, Mon.

THE library of the Royal Medical and Chirurgical Society will be closed during the month of August.

THE Tavistock Cottage Hospital was formally opened on the 25th inst.

AT Canterbury, on the 27th inst., a bazaar was opened in aid of the funds of the Kent and Canterbury Hospital, an institution which is now about £1500 in debt.

A GENTLEMAN of Somerset, who does not wish his name divulged, has increased his gift of £500 to the Extension Fund of the Taunton and Somerset Hospital to £5000.

ON the 21st inst. a conversazione in connexion with the London School of Dental Surgery was held in the rooms of the Medical Society of London, Chandos-street.

PRESENTATION.—Dr. C. J. White has been presented with a silver salver, a purse containing £70, and an illuminated scroll, on the occasion of his leaving Snodland, after practising in that place for seventeen years.

ON the 23rd inst. the managers of the Metropolitan Asylum District made their annual visitation and inspection of the Caterham Asylum for Imbeciles. The result of the inspection was reported to be satisfactory.

AT Finedon, near Wellingborough, a large number of children have been poisoned by fried fish. Some of the sufferers are not yet out of danger, but it is believed that in all the cases fatal results will be averted.

THE Managing Committee of the Birmingham Queen's Hospital have issued an appeal to the public for £10,000, half of which it is proposed to expend on an improvement scheme.

ON the 21st inst. Mr. T. H. Bartleet, the Ingleby lecturer for the year, gave a lecture at Queen's College, Birmingham, on the "Surgical Treatment of the Lower Bowel." The chair was occupied by Mr. O. Pemberton.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.—On the 21st inst., the tenth block of houses for the accommodation of patients at this institution was opened by Princess Beatrice. The new building, which has been erected at a cost of £10,000, brings up the entire hospital accommodation to 120 beds.

DEATH UNDER CHLOROFORM.—A death occurred at the Queen's Hospital, Birmingham, on the 24th inst. during the administration of chloroform to a girl aged seventeen who was about to have an abscess opened. At the post-mortem examination the heart was found structurally healthy, but feeble. A verdict of "Death by misadventure" was returned.

PHARMACEUTICAL SOCIETY.—At a recent meeting of the Board of Examiners appointed under the provisions of the Pharmacy Acts to examine persons desirous of carrying on the business of pharmaceutical chemists and chemists and druggists, thirteen candidates were certified for registration as pharmaceutical chemists, and ninety-one as chemists and druggists.

Digitized by Google

MR. JAMES B. BAILEY, resident librarian of the Royal Medical and Chirurgical Society, has been appointed to the librarianship of the Royal College of Surgeons.

WATER SUPPLY.—Viscount Cranbrook has presented a petition to the House of Lords, and Sir Robert Fowler, Bart., to the House of Commons, from the Water Consumers' Association, calling attention to the recommendations of the Royal Commission of 1868-74 on the Pollution of Rivers, in connexion with the present deficiency of water in many districts, its impurity, and the injurious effects of its hardness as now generally supplied.

THE Italian War Office, preparatory to the military operations impending on the Abyssinian frontier, has established three floating hospitals, each with its medical staff and relative equipment. One of these is to lie off Massowah; the other two will ply between that port and Italy for the transport of the sick and wounded. The hospital system ensures the patient being under the same physician or surgeon from the beginning to the end of his illness.

CITY OF LONDON LYING-IN HOSPITAL.—At a meeting of the Committee of Management, held on Wednesday last, the medical officer, in his monthly report, drew attention to the very satisfactory results achieved in the hospital during the past twelve months. Since that time, there having been 331 deliveries in the hospital without a maternal death, although several cases had caused considerable anxiety, there had not been a single case of septicæmia. This, he considered, most gratifying, as such good fortune had not attended the hospital for many years. The last death occurred early in May, 1886.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At the monthly meeting of the members of this Association on the 20th inst., a communication was read from the Manchester and Salford Sanitary Association suggesting further co-operation among local authorities between whose districts traffic in milk was carried on. Some discussion followed, and a committee was eventually appointed to consider the matter. A resolution was then adopted, on the motion of Mr. Vacher, approving of the proposed federation of Societies of Medical Officers of Health. Dr. H. H. Vernon afterwards delivered an address on the "Practical Results of Sixteen Years' Sanitary Work in Southport."

MEDICAL NOTES IN PARLIAMENT.

Coroner's Bill.

IN the House of Lords on the 21st inst., the Lord Chancellor moved the second reading of this Bill which, he said, was simply a measure of consolidation.—Lord Herschell said he hoped that with this Consolidation Bill the subject of the amendment of the law would not be lost sight of.—The Earl of Selborne, referring to the mode of electing coroners as requiring amendment, observed that as the freeholders of a county elected a coroner, there was a long and expensive canvass, and he knew for certain that the usefulness of some coroners had been permanently injured by the embarrassments into which they had fallen in consequence.—Viscount Cross remarked that when he had the honour of being at the Home Office he brought in a Bill dealing with coroners' elections. He knew the enormous expense of such contests in Lancashire, and he believed that it had seriously affected the usefulness of those offices. He for one would wish to see some other mode of election, but the first step to reform would be the consolidation of the law.—The Bill was read a second time.

Sanitary Condition of Margate.

In the House of Commons, Mr. S. Leighton asked the President of the Local Government Board whether he proposed to take any action in consequence of the official report of Dr. Page to the Local Government Board, stating that "the Town Council of Margate continues in default in not providing for the pressing (sanitary) requirements of their district;" and that "the infant mortality in Margate has during the last five years been 176 per 1000, whereas the infant mortality of the rest of England is 148 per 1000;" and whether it would be possible to provide for the periodical publication of reports on the sanitary condition of other towns by independent medical inspectors of the Local Government Board.—Mr. RITCHIE, in reply, stated that the Board had sent copies of the report to the Town Council and requested that they would at once give it their serious consideration and inform the Board of the action which they proposed to take with regard to the matters to which it referred. The reports of the Board's medical inspectors on the sanitary condition of districts inspected by them were usually printed, and when it was considered expedient they were placed on sale. When a report was in print and not for sale, the Board was always willing to supply copies to persons interested.

Brompton Cemetery.

In reply to Sir A. Borthwick, Mr. Plunket stated that the total burials in Brompton Cemetery up to February last were 135,617, and the yearly average of the last three years was in round numbers 5000. Under the Acts relating to intramural interments the Secretary of State was the authority who decided on the closing of burial grounds, but special provision was made for the keeping open of Brompton Cemetery, subject to rules and provisions laid down by the Home Office. He could not admit that any necessity had been shown for closing Brompton Cemetery.—Sir A. Borthwick gave notice that on an early occasion he would call attention to the subject.

Compulsory Vaccination.

On the 22nd inst., the House being in Committee of Supply, on the vote for the Local Government Board coming under consideration, Mr. A. O'Connor moved its reduction by £16,600, being the amount allocated for public vaccinators. He complained that the system of compulsory vaccination was unfairly administered and had been proved to be a failure, and he especially objected to the system of "rewards" for successful operations.—Dr. Farquharson was strongly in favour of the compulsory system, which had greatly improved the efficiency of vaccination, and thought the system of "rewards" ought to be extended to Scotland and Ireland.—Mr. Picton, Sir J. Pease, and Dr. Clark objected to compulsion, and Mr. Whitbread, who warned the Government that the anti-vaccination movement was spreading, suggested the appointment of a Royal Commission, which he thought would be the best means of laying before the public the new information on the question.—Mr. Ritchie admitted with regret that the opposition to the vaccination laws was not diminishing, but he did not think the number of anti-vaccinators was largely increasing. But he complained of the gross misrepresentations which where disseminated among the non-informed portion of the community. To illustrate the advantages of the compulsory system, he quoted statistics to show that from 1847 to 1853, before vaccination was compulsory, the death-rate from small-pox was 1617 per 1,000,000, but from 1854 to 1871, when it was compulsory, although inefficiently performed, the rate decreased to 817 per 1,000,000, while in 1872 the number of deaths had gone down to 323 per 1,000,000, and it was calculated, he said, that from 1853 to 1880 no fewer than 22,000 children had been saved by vaccination.—Mr. A. M'Arthur, Sir U. Kay-Shuttleworth, Dr. M'Donald, and other members also spoke, and the amendment was negatived on a division by 196 to 66. Ultimately, after a series of interrogatories had been put to Mr. Ritchie by Mr. Pickersgill and Dr. Tanner, the vote was agreed to.

The River Lea.

Mr. Ritchie informed Captain Colomb that the Local Government Board had been in communication with the West Ham Town Council on the subject of the insanitary condition of the River Lea. The Board considered that further inquiries into the matter should be made, and one of their inspectors would attend the meeting of the West Ham Council on Thursday next.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ALEXANDER, ADOLPHUS B., L.D.S.R.C.S.Eng., has been appointed Dental Surgeon to the London Throat Hospital.

ANWYL, H. J. N., has been appointed Senior Assistant Medical Officer to the Kent County Asylum, Chartham, near Canterbury, vice E. W. White, resigned.

BROCKWAY, A. B., M.R.C.S., has been appointed Resident Clinical Assistant to the South-Eastern Hospital of the Metropolitan Asylums Board at New Cross.

BRUSHFIELD, THOS., M.A., M.B.Cantab., M.R.C.S., has been appointed Second Assistant Medical Officer to the Kent County Lunatic Asylum, Chartham, Canterbury.

COWAN, FREDERIC S., L.R.C.P.Lond., M.R.C.S., has been reappointed Honorary Medical Officer to the Royal United Hospital, Bath.

CRADDOCK, SAMUEL, M.R.C.S., L.S.A., has been reappointed Honorary Medical Officer to the Royal United Hospital, Bath.

DYER, BERNARD, has been appointed Analyst for the City of Truro.

ELLIOTT, GEORGE H., M.R.C.S., L.S.A., has been appointed Medical Officer for the Second District of the Westbourne Union.

FIELD, ERNEST, M.D.Aber., M.R.C.S., has been reappointed Honorary Medical Officer to the Royal United Hospital, Bath.

GRIFFITH, THOMAS WARDROP, M.B., C.M.Aber., has been elected Professor of Anatomy in the Medical Department of the Yorkshire College, Leeds.

HARLOCK, H., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Third District of the Westbourne Union.

LEIGH, JOHN D., M.B., C.M.Ed., has been appointed Assistant Medical Officer for the Workhouse of the Township of Toxteth-park.

LONGMAN, ARTHUR, M.R.C.S., L.S.A., has been appointed Medical Officer for the Bishopstone District of the Wilton Union.

MCGILL, ARTHUR F., F.R.C.S.Eng., has been appointed Professor of Surgery in the Medical Department of the Yorkshire College, Leeds.

MORRISON, J. T. J., B.A., M.B., B.C.Cantab., F.R.C.S. Eng., has been appointed Casualty Surgeon to the Queen's Hospital, Birmingham, vice Marsh, appointed Honorary Surgeon.

REID, IRVINE K., M.D., C.M.Aber., has been appointed Medical Officer in the Government Medical Service of British Guiana.

ROBSON, MAYO, F.R.C.S.Eng., has been appointed Lecturer in Practical Surgery in the Medical Department of the Yorkshire College, Leeds.

SHARP, J. A., L.R.C.P.Lond., M.R.C.S., has been appointed Honorary Surgeon to the Derby Infirmary, vice Dolman, resigned.

SPURGIN, WILLIAM H., M.R.C.S., L.S.A., has been appointed Medical Officer for the Schools at Flimby of the Cockermouth Union.

TAYLOR, ALFRED H., M.B., B.S.Lond, M.R.C.S., has been appointed Surgical Registrar to Westminster Hospital.

TIFFEN, C. J., M.D., C.M.Ed., has been appointed Medical Officer for the Wigton District and the Workhouse of the Wigton Union.

VOELCKER, JOHN A., has been appointed Analyst for the Borough of Bedford

Births, Marriages, and Deaths.

BIRTH.

MURRAY.—On the 14th inst., at Swinburne Castle, Northumberland, the wife of William Murray, M.D., F.R.C.P.Lond., of a daughter.

MARRIAGES.

BLOOD—DUDGEON.—On the 20th inst., at All Saints', Blackrock, county Dublin, Joseph Blood, of the Indian Medical Service, to Eliza, fourth daughter of Henry James Dudgeon, of The Priory, Blackrock, county Dublin.

CASSIDI—DUNCANSON.—On the 20th inst., at St. Mary's Church, Dublin, Francis Richard Cassidi, M.D., to Marion E., younger daughter of the late John Duncanson, M.D., of Alloa, N.B.

FITZGERALD—FINUCANE.—On the 20th inst., at Hamilton, Ontario, Canada, Michael FitzGerald, Staff-Surgeon, R.N., to Florence Maria, eldest daughter of Deputy Inspector-General Finucane, R.N.

PITT—HERIOT.—On the 20th inst., at the Parish Church, Harrow Weald, George Newton Pitt, M.D., M.A., M.R.C.P., Assistant Physician at Guy's Hospital, late Fellow of Clare College, Cambridge, to Jane Elizabeth, eldest daughter of Robert Heriot, Esq., of Graemes Dyke, Harrow Weald.

RICHARDSON—REECE.—On the 21st inst., at the Parish Church, Hove, by the Rev. T. Peacey, M.A., Vicar, Adolphus Joseph Richardson, M.A., M.B.Cantab., M.R.C.P.Lond., of St. John's-terrace, Hove, to Kitty H. (Tiny), only daughter of the late Geo. Reece, of Edwardes-place, Kensington.

WEEKS—PRANGLEY.—On the 20th inst., at Aylsham Parish Church, by the Rev. Robt. Hake, Vicar, assisted by the Rev. A. Law, Ernest Alfred Weeks, of Willesden-green, to Muriel Maude (Dolly), younger daughter of Thomas Prangley, M.R.C.S., of Aylsham, Norfolk.

DEATHS.

ATKINSON.—On the 25th inst., at Kew, Surrey, John Charles Atkinson, M.D., aged 76.

CHEETHAM.—On the 20th inst., at Compton-road, Canonbury, Joseph Cheetham, M.D., M.R.C.S., aged 68.

COOPER.—On the 25th inst., at Buxton, Frederick Cooper, H.M.'s late Inspector-General of Hospitals (India), aged 83.

ENGALL.—On the 18th inst., Thomas Engall, M.R.C.S., of Lady Somerset-road, N.W., formerly of Euston-square, in his 80th year.

GRANT.—On the 19th inst., at Lagos, West Africa, Charles Scovell Grant, M.D., Colonial Surgeon.

GREEN.—On the 21st inst., at Lynchmere, Harold-road, Upper Norwood, William Abbott Green, Inspector-General of Hospitals, Bengal (retired), and Honorary Surgeon to the Queen, aged 79.

PRICE.—On the 18th inst., at Pontresina, Switzerland, John Price, Surgeon, R.N., aged 32.

ROWE.—On the 25th inst., at Haverfordwest, Thomas Henry Rowe, M.R.C.S., J.P., aged 47.

STEPHEN.—On the 19th inst., at Windlesham Lodge, Bagshot, Andrew Stephen, M.D., of 58, Queen's-gate-terrace, Kensington, aged 53.

WARD.—On the 1st inst., at Rangoon, George James Ward, M.R.C.S., L.R.C.P.Ed., L.M.D., 5th Bombay Light Infantry, aged 34.

WILKINS.—On the 19th inst., Arthur Frederick Wilkins, M.R.C.S., L.R.C.P.Ed., aged 29.

N.B.—A fee of 2s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

INTEMPERANCE AMONGST WORKMEN.

THE *Concordia* reports the fact that various large employers of labour in Germany have been devising a means of stopping the drinking of brandy by their workmen. The experiment has been tried of distributing coffee gratuitously, and the results have been, it is said, of a satisfactory character.

Mr. J. Martin.—The cases recorded seem quite insufficient to prove injury to health from butter substitutes in the face of the mass of evidence to the contrary. As for the name, "margarine" has been settled by Government and adopted in the Bill now before Parliament, so that it is not easy to see what our correspondent wishes to prove.

Viator.—It is both customary and reasonable for a general practitioner to charge more for visiting several members of a family than for visiting one.

Mr. H. J. Dixon's communication arrived too late for publication this week.

Denver.—The paper has been received.

THE BRUSSELS UNIVERSITY.

To the Editors of THE LANCET.

SIRS,—In the current number of THE LANCET, at page 186, under the heading "Foreign University Intelligence," you have inadvertently published a statement relating to the examinations for the Brussels degree in medicine which is calculated to mislead English practitioners who may contemplate presenting themselves at that University for examination. Permit me to point out to you that not only is the Second Doctorate examination *not* "one of the earlier examinations from which English practitioners who seek Brussels degrees are exempt," but that every candidate, no matter what his nationality, must pass the First as well as the Second Doctorate (which examinations some of the rejected have good cause to remember) before being admitted to the Final or Third.

I am, Sirs, yours faithfully,

July 23rd, 1887. M.D. BRUX., &c.

Mr. B. H. Mumby (Portsmouth) will find much information in Prof. Storer's book, "Agriculture in some of its relations with Chemistry"—a work which will very shortly receive notice at our hands.

IN-DOOR PUPILS.

To the Editors of THE LANCET.

SIRS,—Could any of your readers oblige a brother medical man by informing him of any hospital or infirmary where in-door pupils are taken on moderate terms per annum?—I am, Sirs, yours faithfully,

July 27th, 1887. C. C.

CAMELS FOR THE WOUNDED IN WAR.

At Massowah the Italian Medical Staff have completed a course of experiments with the object of utilising camels for the conveyance of the sick and wounded. Each camel will be so equipped as to carry with the minimum of discomfort three patients—one on the back and two at the sides. Every sanitary convoy is henceforth to consist of one camel and two mules, to transport five sick or wounded.

Mr. S. Grenfell.—The question is too vague to admit of a precise answer. Dr. Marchison's work on the "Continued Fevers of Great Britain," re-edited by Dr. Cayley, deals exhaustively with this question as regards typhoid fever. With reference to scarlet fever and diphtheria, the evidence as to the influence of sewer air in their production—whether that air contains the infection of those diseases or acts *per se*—is mainly embodied in local reports of officers of health. Much the same applies to such other diseases as erysipelas and blood-poisoning. The history of such cases is scattered, and not put together, in so far as this special method of causation is concerned.

Enquirer.—If lymph is to be used within a short period after it is collected—i.e., after a few days,—it is best preserved on ivory points; if after a long period, it is then best preserved in tubes.

Mrs. Clarke had better apply to the Secretary of University College Hospital.

Mr. F. E. Marston.—Tickets were sent to the medical corporations.

"VOMITING PERSISTING FOR YEARS."

To the Editors of THE LANCET.

SIRS,—*Apropos* of the two cases of persistent vomiting alluded to in THE LANCET of the 9th and 16th inst., the following one of twelve or fifteen years' standing may prove interesting to your readers if you will oblige me by inserting it in your columns.

The patient is a lady over fifty years of age, of small frame, thin, and with very soft tissues; naturally of an active temperament; now, of course, greatly subdued by the long and unceasing strain upon her system. She is certainly not hysterically inclined. Her face has a careworn aspect, and its features have rather a pinched and sunken appearance. Her tongue is always moist, foul, and sometimes slightly furred. In the submaxillary region are two soft-feeling glands, clearly defined, and projecting above the surrounding tissues. From these active little organs flows almost a continuous stream of saliva, causing a most annoying ptyalism, and whilst the lady is conversing filling her mouth with saliva. The bowels are always costive, only yielding to an enema. The stools are, however, natural in colour and consistence. There is no history or symptoms of malignant disease or gastric ulcer, except an attack of hæmatemesis many years ago. No complaint is ever made of cerebral symptoms, and the liver, kidneys, and uterus appear to be sound. Digestion is good, Welsh rare-bit being one of the dishes most appreciated by the stomach, which, however, is rather fastidious. I cannot detect that one kind of food causes emesis more than another: I mean foods which are suggested by the appetite. Never a day passes without this capricious organ disgorging a portion of its contents, the attack always being heralded by nausea. The stomach, like an irritable uterus, seems to have contracted the bad habit of expelling as a foreign body its natural burden. I say the digestion is good, because what is vomited is well digested, having the appearance of panado, flotting, however, in an excess of limpid fluid. I can find no sign of enlargement. Sir Andrew Clark, who some time since kindly saw the case with me, thought he did. The body being thin, the slightest deviation from the natural condition of things could easily be detected at the present time. I have tried every so-called remedy in the Pharmacopœia without any appreciable benefit accruing. Peptonised milk is as efficacious as anything, for it is bland and soothing to the organ when more than usually irritable. Effervescing drinks painfully distress the patient. Alkalies to increase and acids to check the flow of gastric juice are alike futile. My view of the case is the following.—That there is a thickening of the pylorus, not necessarily of a malignant character, which only permits a certain portion of the digested food to pass in a given time. The large quantity of saliva which is constantly being insalivated and swallowed disturbs the stomach, thus irritating the diaphragm, and so in the usual way exciting vomiting by its upheavings. In a few words, vomiting is caused by a contracted pylorus and excess of fluid. How much habit is a factor in the operation I know not. Pathologists might smile incredulously if I ventured to be too dogmatic upon this point. Two symptoms are always present—pyrosis and cardialgia, to use an old fangrunous word. According to our present ideas, an overflow of saliva should neutralise acids, but in the case under notice neither saliva nor artificial antacids have any neutralising effect whatever. Whether unnatural distension of the stomach by the excess of a natural stomachic stimulant, nor contraction of its pyloric extremity, produce the constant emesis, we must, I suppose, look further, as in glycosuria, and conclude that some hidden and mysterious pathological condition of the nerves caused little lesion, as the corpus striatum, or optic thalamus of the right side, is the direct cause of the disturbance. I may add that I have failed to discern carcinomatous cachexia, although the vomit certainly seems at times to be a mass of fermentation. Perhaps some of your readers more capable than myself of solving the difficulty may be able to throw some light upon the subject.

I have the honour to be, Sirs, your obedient servant,

Finsbury-circus, E.C., July 26th, 1887. HARVEY J. PHILPOT.

PROPOSED ARTIFICIAL SEA-WATER LAKE FOR SOUTHPORT.

THE gradual retirement of the sea from the town of Southport has long had an unfavourable influence on this pleasant seaside resort. We have before us a scheme invented by Mr. Lightowler, a Southport tradesman, and developed by Mr. B. H. Thwaite, C.E., of Liverpool, that is intended to minimise the defect mentioned. Mr. Lightowler's scheme consists in the construction of a dwarf breakwater of a novel sectional form along the beach, in such a position that during abnormal or spring tides, or when the water at rare intervals reaches nearly to the esplanade, the water accumulated therein, or behind the breakwater, is retained, and cannot escape, except the sluice-gates provided are opened. The breakwater is constructed of such a height as to retain water of an average depth of, say, 2 ft. on the inside of the breakwater, and such water would then form a lake of a superficial area equal to 201 acres, and form a healthful adjunct to the town of Southport. The breakwater is designed so as to provide a drive of six yards in width. The sectional form of the breakwater, which is intended to be constructed entirely of Portland cement concrete, possesses some novel features. It is hollow in section, and provides a silt depositing canal for the collection of the silt sand and offensive organic matter brought forward and held in suspension by the sea water when in motion, but which are deposited when the water is in a quiescent condition in the depositing canal. By this means the artificial lake is kept pure. The height of the proposed breakwater is such as not to interfere with the seascape, and the reach of sand between the breakwater and the line of sea at low tide would be lost in the line of sight of an observer standing on the esplanade. Consequently, the sea would appear to reach continuously up to the foot of the esplanade. The advantages of what is practically the bringing of the sea back to Southport will be obvious to anyone, and its applicability to seaside resorts similarly situated to Southport need not be dilated upon.

Puzzled.—The circumstances detailed by our correspondent are very annoying. It is to be regretted that, on seeing the letters, and especially on seeing the individual, "Puzzled" did not decline his services. He should see the gentleman who recommended the *locum tenens*, and if the representations concerning the qualifications are false he should refuse the fee claimed, if not undertake proceedings to expose the individual in question. If, on the other hand, he possesses such qualifications, we should recommend our correspondent to pay. It is always unwise to enter into such arrangements without both seeing the person and having the most definite understanding with him as to terms in writing.

Probang.—Such a practitioner can only enforce payment on account of surgical cases. He can keep an open surgery.

450 has not enclosed his card.

TREATMENT OF LUPUS.

To the Editors of THE LANCET.

SIRS,—Dr. Drewitt, at the meeting of the Clinical Society of London on May 27th last, stated that he had used salicylic acid and creasote with good effects in lupus. Would Dr. Drewitt kindly state the proportions of the application and the method, &c., of applying, as I have a very obstinate case in hand.—I am, Sirs, yours faithfully,

WILLIAM H. MACDONALD, M.D.

Antigonishe, N.S., Canada, July 11th, 1887.

Dr. T. P. Smith.—There is, as far as we know, no restriction as to the length of the essays. It would be well for intending competitors to write to the Secretario de Gobierno, Calle del Triador, No. 11, Valencia, for details as to the conditions of the competition.

Mr. T. Laffan.—The hon. secretaries may be addressed, 61, Kennington-park-road, S.E.

Taxpayer will find a letter on the subject in THE LANCET of December 6th, 1884.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Gant, London; Surgeon-Major Doble, Kamptee; Dr. W. E. Steavenson, London; Mr. Vincent Jackson, Wolverhampton; Dr. A. H. Hassall, Lucerne; Sir G. H. B. Macleod, Glasgow; Dr. Gowers; Mr. Godlee, London; Mr. H. A. Reeve, London; Dr. Purcell, London; Mr. A. F. Mickle, London; Messrs. Holmes, London; Surgeon-Major Bethe; Dr. W. H. Macdonald, Antigonishe, Canada; Messrs. Macmillan and Co., Cambridge; Mr. A. G. Bateman, London; Messrs. Richardson and Sons, London; Mr. D. ABSTRACT OF

The Address in Medicine,

Delivered at the meeting of the British Medical Association at Dublin.

BY W. T. GAIRDNER, M.D., LL.D. ED.,

PHYSICIAN-IN-ORDINARY TO HER MAJESTY THE QUEEN IN SCOTLAND, PROFESSOR OF MEDICINE IN THE UNIVERSITY OF GLASGOW.

DR. GAIRDNER commenced his address by observing that anyone who had acted as a teacher of medicine had been in the habit from year to year of surveying officially the healing art as a whole. He had watched the rise and fall of doctrines, of methods, of tendencies and currents of opinion. He had come, or ought to have come, to see that there has been an evolution of the art going on in his time; an evolution not at all the work of any one man or of any one school, but rather of what Matthew Arnold and the Germans call the *Zeitgeist*—the spirit of the age. It seemed to him the possible theme of an interesting address to seize upon those aspects of the subject which most revealed that inner spirit, and to expand them so as to give a vivid conception of whither we are tending, or how, and by how much, we differ from our fathers. The field was, Dr. Gairdner said, vast, and we recoil instinctively from the conclusion that it was a mere aggregate of laborious investigations, guided by no common purpose, no fixed or polar star. It must, however, be confessed that the various doctrinal systems of the past, and not a few of the gross charlatanisms of the present, have had a seductiveness for the public and even for some minds in the profession itself, founded mainly on the notion that here at least—viz., in the particular formula, or perhaps exclusive remedial method advocated—is to be found a ruling principle, a law or compendious statement of doctrine intended to illuminate every corner of the art of medicine; hence that physicians are bound to bring all their accumulated stores of knowledge into court, and make them all do homage to this one doctrine, one law, thus set forth as the only true law of the healing art. To such a universal proposition, when made, there can be only one answer. No such exclusive or single principle or law of the healing art can be said to exist; the action of remedies, the resources of hygiene and of preventive medicine, refuse to submit to any formula comparable in its simplicity with that of the law of gravitation. After referring to an address delivered in 1875 by the late Dr. Warburton Begbie, in which an answer was given to the question by the late Sir William Hamilton, "Has the *practice* of medicine (that is, the art as distinguished from the science) made a single step since Hippocrates?" and to the work of Cullen and his controversy with John Brown, Dr. Gairdner, referring to the instability of the medical art in Cullen's time, said that it seemed as if the medical mind, oscillating between the claims of humoralism, solidism, and vitalism, could find no resting-place, but was constantly exposed to be drawn out of the path of traditional medicine by any new theory which presented a certain amount of apparent simplicity and plausibility—all the more if it contemptuously dismissed, as unworthy of serious study, the laborious and positive acquisitions of clinical and pathological fact which had even then been largely gathered in, especially by Morgagni, as to the natural history of disease; and this was exactly what the Brunonian system did. Since Cullen's time, however, the progress of modern medicine has been in the direction of *stability*—a kind and degree of stability not possessed by the art of medicine in any previous state of its progress—not even in those "dark ages," as we call them, when it had the prestige of a kind of immutability, or, as a theologian would call it, orthodoxy, founded on the overwhelming authority of Galen.

To take a single illustration from surgery, which was out of the direct line of his inquiry, but which could not fail to be a striking one: it was not open to him even now to claim for antisepticism, in the strict sense of the word, the credit of an advance all along the line, because we have eminent surgeons among us who claim to obtain, and he believed do obtain, brilliant results without using the particular remedies called antiseptics; and therefore the theory of antisepticism, and the separation of what is permanently from what is only incidentally true in this great issue, was a research of no small complexity, and perhaps of extreme difficulty for a professor of medicine, who nevertheless believes, as he does, that the impulse communicated to surgery through antisepticism is one of the greatest in the history of the art. And yet it was surgery which, as respects the more tangible and obvious character of its processes and results, has been humorously defined as, *Quod in medicinâ non dubium.*

As regards that great revolution in the medical treatment of fevers and inflammations, which in some minds occupies in relation to medicine as advanced a position as antisepticism does in relation to surgery, Dr. Gairdner said that it had not as yet been made quite clear to his mind by evidence, statistical or other, that the treatment of any fever or inflammation by such means as were recorded some years ago by Liebermeister and Jürgensen, the one as regards typhoid fever, the other as regards pneumonia, had resulted in a permanently lessened mortality when set against results obtained or obtainable in this country, without these very active procedures. Having stated his opinion to this effect some time ago, however, he felt bound to add now that he was by no means insensible to the wonderful patience, research, and apparently scientific exactness shown by these authors in their latest researches on the subject. Certain modifications of the practice had also tended towards the removal of distrust, and should another great epidemic, say of typhus fever, occur in Scotland, he should very gladly witness or concur in a therapeutic experiment such as would practically settle the question. In the meantime, however, he must regard the antipyretic treatment in all its various forms as still under controversy.

No one having any familiarity with modern medical practice could overlook the large place occupied in it by certain powerful, and it would be hardly too much to say indispensable, remedies acting on the nervous system, many of which are entirely modern. The most prominent and perhaps also the most unquestionable of these was chloroform; and if forty years could ever be regarded as sufficient for testing an advance in medicine, or surgery, it might be safely affirmed that the reputation of our day and generation might be regarded as saved by this one great achievement. Yet there were not wanting evils to be discounted, and failures to be set against the benefits of this enormous boon to the suffering human race; and it would not surprise him to find that there exist, even now, well-informed persons who believe that the lethe which comes from modern chemicals, like that which of old was born of poppy and mandragora, has been a questionable advantage to humanity at large. What then should be said of hydrate of chloral, butyl-chloral, paraldehyde, urethan? and what of the condensed forms, or alkaloids of the older narcotics, so immensely convenient, but also so powerful for mischief? He for his part had no doubt that the balance inclines, at least in instructed medical hands, greatly in favour of the service these remedies are doing, and may yet do, to great numbers of the sick, and especially the fatally afflicted members of our race. Again, the modern use of digitalis, strophanthus, and other cardiac tonics; and again, the use of nitrite of amyl and of nitroglycerine in angina pectoris and the allied conditions: Who was there that doubted that in these, when well employed in judicious and well-instructed hands, we have obtained a very distinct and very valuable addition to our resources in cardiac diseases? And yet was there anyone who would expect him to prove this in an unassailable manner, to the satisfaction of a sceptical friend or foe, within the limits of his present address?

Again, the benefit derived from the salicyl compounds in acute rheumatism was to his mind very satisfactorily established, and he should be personally disposed to claim this as a very distinct advance in the healing art within a comparatively recent period, and a partial removal, moreover, of one of the old *opprobria medicinæ* which he had lived long enough to have been obliged, over and over again, to recognise as such. But would anyone say that his simple assertion of this could reasonably outweigh all the sceptical or contradictory statements on this point which it might be expected to call forth? Evidently, in regard to remedial agents and processes not more than twenty years old, it was vain to expect such a concurrence of opinion as to entitle anyone to set them forth dogmatically, as the permanen

Digitized by Google

and unquestionable milestones in our progress, which future ages too might be expected to acknowledge as such. In considering stability, therefore, we have not only to lay our account with possible new discoveries, but also with the perhaps unknown or unappreciated dangers attaching to practices now vaunting themselves in the full sunshine of apparent prosperity and success. While, therefore, he had and professed the most entire faith that the efforts of hundreds of young and enthusiastic workers are being fruitfully directed towards a science of pharmacology, on the joint bases of experimental research and scientifically directed observation, we are still, he feared, too much in the transitional stage to allow of many of these researches being adduced in evidence of the increasing stability of the medical art. Rather might it appear to some as if the multitude of new remedies which come to us from all the ends of the earth, the too brief reputation of some of these, and the evidently over-sanguine estimates of others, were the proofs of an unrest which was quite the reverse of stable; which could not be satisfied with the old remedies, old prescriptions, old methods of cure; but holding itself bound to drive on the *currus triumphalis* of modern therapeutics at all costs, was likely to land us once more in a new series of controversies such as attended the famous work of Basil Valentine on the healing virtues of antimony, perhaps three hundred years ago.

But he held, and had never ceased to hold, as a teacher of medicine, that all this fermentation, so to speak, of opinion with respect to current remedies and modes of treatment, all these tokens of unrest and dissatisfaction, were, in reality, an advantage to the medical art, and tended both towards progress and towards stability; an altogether different kind and measure of stability, however, from that implied in the authority of Galen, or the traditions of the Greeks and Arabians.

Dr. Gairdner hoped to be able to show that there were some points of our progress in which the dissolution or weakening in their hold of what he called orthodoxies had been accompanied by a truly constructive process, and that the new theory and corresponding practices which had displaced the old differed from it in this, that, being the result of applied science and not of mere tradition, they were correspondingly secured against revolutionary overthrow.

1. *Hygienic remedies.*—The fruitful and, he thought, the unquestioned progress of preventive medicine (otherwise called sanitary science) during the last thirty or forty years was not only a very striking advance in itself, but it might also be maintained, he thought, without contradiction that curative medicine had largely and quite steadily advanced along the same lines. The prevention and the cure of disease were not, indeed, identical, but the laws which guide the former were in a large measure, and necessarily, applicable to the latter. The same noxious influences which beget typhoid fever, for example, tended in a remarkable degree to exaggerate, if not to cause, a host of minor diseases, and very notably to increase the risks of the healing of wounds and of the puerperal process. The same overcrowding which was in a great degree the cause of typhus fever was a source in hospital wards of pyæmia and erysipelas, in barracks and gaols of consumption (and this often among picked men), in certain endemic localities of contagious pneumonia, and probably of diphtheria. It was impossible, in the face of modern sanitation, to escape the conclusion that the causes and the remedies of disease alike were often to be sought more in the study of groups and even of multitudes of cases than in the ordinary text-books, or in the conventional remedies set down for the particular *nomen morbi*. In short, the treatment of diseases of every kind had been largely, even if silently, influenced by the thought that the chief disease-breeding factors must also be, in individual cases, adverse influences to be carefully studied and kept in check by those who would cure disease, and that, in chronic cases especially, a large part of the cure consisted in the removal or modification of the injurious action of the cause. The changed point of view implied in the more fruitful and practical study of causes had in many cases made it impossible to cling to the old and traditional aspect of certain diseases as entities, arising we do not know (and do not strive to know) how, and only to be met by a *farrago remediorum* addressed to individual symptoms, or, at least, directed to the consideration that a morbid influence, or something unknown, had got to be battered down in the recesses of the economy by sheer expenditure of therapeutic violence, at whatever cost to the physiological functions of the sufferer.

2. *Self-healing processes in acute diseases: abuses of venesection.*—Closely allied with this change, which he took to be a permanent one, making in the direction of stability for the medical art, was another which had come to a head, or at least had begun to bear fruit largely, only within his own recollection, and which he could distinctly recall as most powerfully influencing his own mind and practice from the very earliest period of anything like independent thinking about it. He did not wish, even for a moment, to lose sight of the fact that the irrational orthodoxies (as he ventured to call them) of the past have been unsettled, very largely owing to the prevalence and the countervailing influence of certain heresies, of which no rational mind could approve. But it was one of the privilegs of our art in its more advanced and, as he thought, more stable condition in this day of ours, that where there was no orthodoxy there could be no heresy (in the old ecclesiastical sense of the term), or, rather, that our freedom of opinion was such that we could afford to absorb into our daily practice, and even into our theories of disease, the instruction that came even from the most erratic and monstrous of heresies, no man making us afraid. Forty years ago, for example, it was still a point fairly open to question whether pneumonia and other acute inflammations could possibly be cured without blood-letting. All knew what had become of this burning controversy, and how completely the old traditional theory, as it came down from Cullen and Gregory, had been overthrown; but it was surely a cardinal instance of the essential instability of that theory that, after being for a time supplanted in Cullen's own day by the ridiculous extravagances of a vainglorious charlatan like John Brown, it should have been reinstated in greater power than ever as regards this particular point in therapeutics, only to be subverted once more, and more completely, by a far better man, the late Sir John Forbes. He it was first who, becoming distrustful of the old tradition, and anxious to learn in a genuine spirit of scientific humility about "nature and art in the cure of disease," did not refuse to accept truth, even at the hands of homœopathists and others, not much, if at all, superior to the Brunonianists of Cullen's day in their claims upon genuine medical science.

3. *Epidemic fevers: alcoholic stimulation.*—Dr. Gairdner then briefly reviewed the treatment of fevers during the past fifty years, and the use in them of alcohol, and said that it might now be regarded as a position established by evidence that in typhus fever, and therefore, *a fortiori*, in other fevers and in all diseases attended by febrile debility, alcoholic stimulants were not the only nor yet the best form of alimentation; that their proper use was as medicines, and this within limits; and that, as a rule, and also within such limits as are suggested by reason and easily attainable in practice, milk (which during the alcoholic fanaticism had been nearly lost sight of) was in reality the food which was for the most part more easily digested and more conducive to success than almost any other. He had thus, he said, endeavoured to show by a few instances only, in what manner, and on what lines, the art of medicine has been advancing towards stability, and concluded by assuring his hearers that what had been done in all these years since Cullen's time had not been in vain. A vast army of earnest unprejudiced and disciplined workers had been engaged upon all the unsolved problems connected with disease. Diagnosis and pathology had made immense strides in advance during nearly the whole of the present century. Operative surgery had achieved the most brilliant and unquestionable triumphs of any period in the long course of medical history, and this in almost every department. Hygiene and sanitation, with their reflected influence on curative medicine, had advanced by leaps and bounds; and, even in the application of strictly therapeutic methods, the changes, though not so easily stated or so palpably appealing to the judgment of public opinion (inasmuch as quackery always was and always would be more self-asserting than truth), were all in the right direction. Polypharmacy in its old and irrational forms was now nearly gone. Hardly anyone of intelligence supposes nowadays that a disease is to be slain by a mere prescription or Latin formula. A science of pharmacology, or of the uses and actions of medicines, was being built up upon a foundation that was never even possible before the present day, and which, beyond all question, would render this, the least satisfactory department of the science of healing, far more secure in the future. The mere simplification in the forms of remedial agents, and the mitigation accordingly of the old, inexpressibly repulsive, and nauseous manner of pre-

Digitized by Google

scribing them wholesale (which incurred the ridicule of Molière two centuries ago, and yet lived on into almost our own day), represented an advance by no means devoid of importance as regards the comfort of the individual patient and the peace of families, and especially of nurseries. Nor was the immense relief to human suffering by the use of anæsthetics rightfully employed, and even of narcotics and anodynes in greatly improved forms of administration, to be lost sight of, even in the most brief allusion to the modern use of drugs.

All that removal, moreover, of the old traditional dogmatisms to which he had referred had been merely a clearing of the ground, so to speak, on which a modern science of healing, not by any means forgetful of its past history, but entirely unshackled by its old errors and prejudices, was being slowly but surely built up. And the fervid youth of the present generation, if they remained true to the spirit and not to the mere letter of the Hippocratic medicine, might well be grateful to their fathers and their grandfathers, were it for nothing else than this important and necessary process, whereby a soil had been prepared, at much cost of individual labour and sacrifice, on which they were permitted and privileged to sow the seed, and to reap more or less fruitful crops of good for humanity at large.

ABSTRACT OF

The Address in Surgery,

Delivered at the meeting of the British Medical Association at Dublin,

BY EDWARD HAMILTON, M.D., F.R.C.S.I.,

SURGEON-IN-ORDINARY TO THE LORD-LIEUTENANT OF IRELAND, PROFESSOR OF SURGERY IN THE ROYAL COLLEGE OF SURGEONS OF IRELAND, AND SURGEON TO STEEVENS' HOSPITAL, DUBLIN.

DR. HAMILTON commenced his address by remarking on the fact that twenty years had passed away since the place which he that day occupied was filled by one of the brightest ornaments of British surgery, Robert William Smith, and thanked the Council of the Association for permitting him to follow, even after such a lapse of time, so distinguished a pioneer. In such an address as he was expected to deliver, the mind, Dr. Hamilton observed, instinctively turned to a retrospect of improvements in surgery or a critical inquiry into the nature of the work which is actually being done amongst us, and so suggestive a theme possessed many attractions, although much of all this had been anticipated in the annual digests to be found in our periodical literature. Engaged in the constant work of a general hospital and the daily routine of metropolitan practice, he could not lay claim to any special opportunities, nor was there any subject on which he had attained that degree of proficiency which would justify him in undertaking the instruction of the able thinkers he was addressing.

He who wrote the history of the surgery of this Victorian era would find one or two cardinal facts of such vast and stupendous proportions as to dwarf all others in the influence which they had exercised on our surgical work. *Facile principe* among these was the method known as the antiseptic system, still enveloped in clouds of uncertainty and misconception, notwithstanding the work which so many eager and enthusiastic inquirers have bestowed upon it, far indeed removed from any approach to finality. It might not be unprofitable to determine what is the present actual condition of this system, and, setting aside bogus theories and misunderstood hypotheses, to ascertain its exact relation to our every-day work. For, after all, it must come to this important question—What help does antisepticism afford to the daily practice of surgery? No honest or impartial observer could fail to recognise with a deep sense of gratitude the magnificent results and the brilliant success which had attended the Listerian system—results which had led to its adoption throughout the civilised world—results which had revolutionised surgical methods, and given a startling impulse to the conservative treatment of injury and disease. The system might be wrong in practice, and founded on an erroneous theory, but that wonderful results had followed since its introduction was an historical fact beyond contradiction. And yet, with this triumphant record, we find some of its most devoted adherents now relaxing the stringency of its application and abandoning parts of the system which were long regarded as essential, and that, too, without any diminution of successful results. Again, we find antiseptic precautions so little regarded—nay, almost set at nought—as to prompt the ovariotomist to flush the peritoneum with water containing "*germs and spores and thirty different kinds of beasts*," and yet point to a continuous record of success little if at all inferior to the more complex method. In this burning controversy, to what conclusion could the simple inquirer after truth arrive at—he who is anxious to decide what is best for those who entrust to his judgment and skill the safety of their limbs and their lives?

It might be conceded as proved by the actual observation conducted and recorded by competent authority, that the atmosphere which surrounds our globe is infested with myriads of minute organisms—call them by whatever name one pleases; that they belong, some to the vegetable, some to the animal kingdom; that they possess vitality, either potential or actual, from which it follows that they are subject to constant and restless change—the heirloom of organisation. These changes are largely influenced, if not altogether caused, by the surroundings among which they are situated, and they in their turn reciprocate and produce disturbance in the material which environs them. It has also been established beyond controversy that some of these microbes are incapable of development or growth in the tissues or fluids of the living body, and can only undergo their life changes when surrounded by material which is dead, and therefore amenable to the physico-chemical laws. Others, again, are capable of maintaining their independent vitality in living tissues, where from a minute beginning they increase and multiply, disarranging and vitiating the entire organism into which they have found their way, waging a deadly war against the tissue cells, who, nobly acting on the defensive, throw out breastworks to resist to the utmost the encroachments of these merciless invaders. In the first variety the effect produced is in direct proportion to the actual amount of the ferment introduced. In the second, the amount of disturbance is out of all proportion to the minute quantity of the noxa which produces it. That these latter bodies are an efficient and potent cause of suppuration and infective inflammation would appear to be proved by actual demonstration. He would not weary his hearers with details, but simply state the experiments which had brought conviction to his own mind. We have experiments which prove beyond doubt that injury may be inflicted on the deep tissues of the living body, either by mechanical, physical, or chemical noxæ; and if due cleanliness of the instruments is observed and atmospheric air absolutely excluded, no effect whatever is produced beyond the injured spot. Hueter of Greifswald injected a 5 per cent. solution of chloride of zinc, killing the tissue with which it came in immediate contact, the necrosed mass producing no ill effect upon the surrounding structures. Like results followed the action of the hot iron.

Chauveau adopted for his experiments the continental mode of castration, by torsion of the spermatic vessels (*bistournage*) by which the organ becomes completely detached from its living connexion, without inflammation, suppuration, or sepsis, in thousands of cases; but if the minutest portion of fluid containing these atmospheric atoms were injected under the skin, so that they entered the blood current, severe inflammation was at once developed, a seething focus of disease where all was peace, and subsequent examination showed the organ and its surroundings infiltrated with infecting germs. These experiments and observations proved conclusively by positive and negative evidence that these aerial entities were capable of producing suppuration and infective inflammation. It had not, to his mind, been established that they were the sole and only origin of such phenomena. But the facts determined by Ogston, Köcher, and others, that they may enter the interstitial tissues through the respiratory or digestive tract, were gradually narrowing the ground uncovered by their influence, and explain away the apparent spontaneity of such diseases as ulcerative endocarditis and infective peritonitis, when these atoms are found crowding the deepest organs without any wound or breach of surface to account for their entrance. If the history which he had endeavoured to sketch be true, it must commend itself to the ordinary

Digitized by Google

understanding that it is our duty to destroy and exclude them from the body with all the care we possibly can; and if the means adopted for that purpose—call them Listerism, antisepticism, surgical cleanliness, or by whatever name we will—turn the scale a feather weight in favour of restoration to health or saving the life of a single human being, the man who refuses to employ them through prejudices or apathy incurs a responsibility nothing short of criminal. The difficulty which is now exercising the minds of practical pathologists and chemists is to find the most suitable germicide—one which will act efficiently without being poisonous to the tissues or the system at large; and it was interesting to watch how one after another they have been lauded and proclaimed, only to be superseded by another and another; and here at all events we are very far removed from finality. Carbolic acid, corrosive sublimate, iodoform, thymol, have each for a time enjoyed the crown for a few months, only in their turn to be deposed and dismissed as impostors with ignominy.

There is, however, another side of antisepticism which has been almost entirely neglected. It would appear as if, up to the present, attention had been exclusively fixed on infective germs, sufficient regard not being had to the important influence of environment. Every effort has been strained to discover the most infective and deadly germicide, when we know that these atoms, no matter how virulent they may be, cannot undergo their life changes, cannot produce these infective results, unless the environment, like the cultivation liquids of the histo-pathologist, was capable of developing and sustaining these changes. Deposited on clean metal, glass, or porcelain, they died of inanition; they exercised no influence whatever, and were amenable to none. In contact with dead organic matter, or living matter in certain conditions of altered or reduced vitality, they become a teeming source of infection, decomposition, and decay. If pathological surfaces could possibly be brought to and maintained in such a condition that they would not afford a suitable cultivation ground, would not almost as much be accomplished as when they are destroyed? He need hardly, Dr. Hamilton interpolated, quote examples of this influence of environment, such as the protection afforded by vaccination against the germ of small-pox, and the protection of the blood by previous action of exanthemata. The bacilli of splenic fever, so destructive to the herbivorous animals, take little effect on carnivora, and none at all on the pachydermata. The bacteria which will cause septicæmia in the mouse are wholly inert against the field mouse. We could learn much that would enlarge our views if we studied human by comparative pathology, and our researches must not be confined within the narrow limits of even the animal kingdom. Much can be learned by the pathology of the vegetable kingdom. Some of the most troublesome diseases which the surgeon has to deal with are derived from the invasion of vegetable parasites.

In connexion with the influence of environment, Dr. Hamilton related a remarkable fact which had been communicated to him by a friend who devoted much time and patient industry to the cultivation of fruit, and which he thought explained many facts in human pathology. In exhibiting fruit for prize competition, they have to be brought to a certain degree of ripeness to a day, almost to an hour, and the ripening can be hastened with almost mathematical precision by interposing between the prize specimens fruit of the same species which were already ripe, as if the emanation from the ripe fruit produced a ripening impression upon the apples in its immediate vicinity. He thought we saw this principle of environment frequently illustrated in human pathology when disease extends to adjacent but not contiguous surfaces. This twofold aspect of infective inflammation was forced on his attention when trying to think out the best mode of dealing with chronic abscess—a subject which has for a long time taxed the ingenuity of the surgeon, and often defeated his most ingenious plans, no matter how carefully they may have been carried out. This might be gathered from the long list of methods provided in our systematic works on surgery. There was nothing which indicated the uncertainty of our knowledge so much as the multiplication of modes of treatment; witness the hundred-and-one ways in which it is proposed to deal with so simple an accident as a broken collar-bone or a fractured femur. The structure of the immediate wall of a chronic abscess has been the subject of much diversity of opinion, and there is considerable doubt as to the existence of any such structures as the so-called pyogenic membrane or cyst wall. The idea of Billroth, that an abscess is but a hollow ulcer, conveys probably an accurate description of its structure. Its action as an absorbent surface is frequently brought under our notice, but its power of pyogenesis is not in accord with modern pathology. There was a fact of very great interest in this connexion. The discharge from a recently opened chronic abscess does not contain the microzymes which are so characteristic of purulent matter in acute suppuration. Ogston and others have failed to detect them by the most carefully conducted observations, or to produce septic results by them; and hence it is that the collections produce little or no constitutional disturbance until they are opened. They may remain for years without any effect other than mere local inconvenience until the matter is discharged—either by the efforts of nature, or by the knife of the surgeon,—and the repeated observation of this fact has induced the surgeon to postpone any interference, waiting often too long for the slow process of natural opening. The clinical records of these cases would lead us to believe that in some remarkable way the system would appear to be somehow prepared for this event; and he was satisfied in his own mind that far less constitutional disturbance follows the natural opening than that effected by the surgeon. There could be no doubt the use of antiseptics has done much to reduce this difference, but he could not say, as the result of his own experience, that they had completely removed it.

Dr. Hamilton then briefly reviewed his plan of treatment of chronic abscesses, and, condemning the Vivisection Act, concluded by appealing to his hearers to make the best use of the means at their disposal and to carry forward the standard of investigation into new and unexplored fields. There was, he said, ample room and verge enough for work—many untrodden fields of discovery—so that they could make the future of Queen Victoria's reign as glorious in the annals of scientific discovery, as full of help to the sick and wounded sufferer, as had been its past.

NOTE ON THE USE OF DRAINAGE TUBES.

BY HERBERT W. PAGE, M.C. CANTAB.,
SURGEON TO ST. MARY'S HOSPITAL.

IN THE LANCET a few weeks ago (vol. i. 1887, p. 947) was a very interesting note on the "Value of the Hæmorrhage in the Treatment of Wounds," wherein was set forth the opinion of Professor Turazza that hæmorrhage, provided that it be not due to the lesion of large vessels or carried to excess, is of small importance, and does not interfere with primary union. And as the outcome of his experience, the following "new rule" in surgery was formulated: that "in wounds perfectly disinfected, and free from foreign substances, the effusion of blood is not a source of danger, but the reverse, for the extravasated blood fills up the cavity of the wound perfectly, preventing the formation of empty spaces, and rendering both compression and drainage superfluous, and further, the organisation of the clot favours healing." Holding these views, the note tells us (for I have not seen his original paper) that he almost entirely discards the drainage tube, "because it increases septic risks, and may remove from the cavity into which it is inserted fluids which in an aseptic condition may be useful by reabsorption."

It would be instructive to know what is nowadays the general practice of surgeons with reference to the point of procedure here recorded. That the amplest possible drainage is ever necessary in cases of suppurating wounds, or of wounds which cannot from various circumstances heal by first intention, is, of course, an accepted doctrine; but it is a question—and with this question I now wish to deal—how far the drainage tube is really necessary, or for what length of time it should be used in the case of wounds inflicted by the surgeon under perfectly aseptic conditions. About the time that this paragraph appeared I had an amputation below the knee performed under not the most favourable conditions, in which the presence of a large blood clot did unquestionably seem to be of value in, or at any rate to cause no interference with, the healing process. This was the case of a woman, aged fifty, in whom a very bad displacement after fracture of the lower end of the tibia and fibula was gravely increased by a violent attack of delirium

Digitized by Google

tremens, and in whom it was found impossible to bring the bones into apposition or to secure union. Efforts in this direction having failed, her leg was removed below the knee on May 10th, two months after her accident, by lateral Stephen Smith flaps — a method of flap-formation, by the way, which is highly to be commended in amputation at the seat of election. The position of the flaps rendered a drainage tube unnecessary, although a very large amount of oozing was expected from the œdematous state of the tissues. The oozing of blood was very great indeed, but in the course of forty-eight hours, at the second dressing, it was seen through the opening which had been left at the most dependent part of the wound that the flaps were filled and distended with a large blood clot. This clot was subsequently watched with much interest. The skin healed by first intention, and at no time was there any pus. The clot gradually contracted in size, and became firmer and firmer, and it clearly aided largely in the filling up and consolidation of the stump, which was perfectly sound and firm when the patient left the hospital on June 16th. The stump had then, in fact, the appearance of one which had been formed for several months, and was absolutely free from discomfort. There can be no doubt, I think, that in this case the blood clot did what Professor Turazza claims for it, and it raises an important question as to the use of the drainage tube. Speaking as the result of general observation and experience, and without reference to any particular case, I should say that the sooner a drainage tube is removed the better is it for the healing process — that is, in aseptic wounds inflicted by the surgeon. The drainage tube performs its office of carrying off superfluous blood and sanguineous serum in the course of from sixteen to twenty-four hours. If its margins have been accurately adapted, the skin wound is healed in this time—sufficiently healed, that is, to render the parts beneath occluded from the air,—and any subsequent extravasation of blood, of which there is sure to be some in the course of the next forty-eight hours, will be dealt with by the tissues, as the tissues ordinarily deal with blood poured out in a true subcutaneous injury where there is no communication with the outside. Some of this blood will be reabsorbed, some—perhaps the greater part—will clot, and organisation forthwith proceeds in this blood coagulum, which fills up all the nooks and crevices of the wound. The clot acts as a sort of scaffold for the building up of new tissue; in other words, organisation takes place on it and in it, and the process of union, of healing, and consolidation is much helped thereby. If the drainage tube be left longer than the time named it is very prone to act as a source of irritation, and I feel sure that it is the frequent cause of suppuration and of apparent failure in antiseptic methods, simply because it has been retained too long. Seeming to act with perfect and needful efficiency because of the visible discharge on the dressings, it is all the while merely carrying off the fluid which itself has caused the tissues to exude. Professor Turazza would discard the tube altogether, and encourage the collection of blood and formation of clot, and his opinion clearly deserves the consideration of surgeons. Without going as far as he, I would say that each case must be dealt with according to its own conditions, and by no hard-and-fast rule. After some wounds no drainage tube is obviously needed, but in the large majority of cases where it is, the early removal of the tube will, I am convinced, conduce to the healing process and lessen the risks of failure and of suppuration. Accurate apposition of the skin, a dry dressing, and perfect rest—these are the essentials for rapid healing in the presence of ordinary cleanliness, by that obtained by purification of water, or with this or that antiseptic solution. With these precautions, and the very early withdrawal of the tube, the immediate healing of a wound seems, in my experience, to be a matter of almost absolute certainty; it matters not whether it be the extensive wound in an amputation of the thigh, an excision of the knee or the excision of a large breast, or the smaller wound such as is inflicted in the operation for strangulated hernia or the removal of a small lipoma. The surgeon secures the immediate closure of the wound, and the inflammatory action which may be set up in deeper parts by the injury of the operation goes on under subcutaneous conditions. We only need to use the drainage tube for the removal of that fluid which, if excessive and confined, will interfere with the perfect rest and approximation of the divided tissues. The use of the tube for this purpose is rarely demanded for more than from sixteen to twenty-four hours, and the method of its *gradual* removal by cutting it a little shorter day by day is, I think, vastly inferior to that of its bodily removal at the end of the first day, or at the first dressing on the day after the operation, in less than twenty-four hours, even if its presence beyond this time be not positively injurious to the tissues and does not interfere with the process of healing.

The antisepticism of modern surgery has sometimes been derided, and it has been held that the drainage tube is the real source of all the good which is to be had from antiseptic treatment. The spray has had its day, and it will be strange if the drainage tube is to follow it. *Pace* Professor Turazza, I find it hard to believe that the drainage tube will disappear entirely from use, even in aseptic wounds. Experience, it is more probable, will lead to its being employed with greater discrimination and caution, and with better adaptation of means to ends, than heretofore; and towards this desirable result (for by it we shall have greater certainty in the healing of wounds) the paper of the Italian surgeon on the value of the hæmorrhage in the treatment of wounds cannot be without influence.

NOTES ON ULCERATIVE ENDOCARDITIS.[1]

By HENRY McCLURE, M.D.

ANY contribution to the literature of ulcerative endocarditis must prove interesting to the profession, and the two cases I am about to give should prove doubly so by reason of the recovery of the patients. The first case is a recent one, the duration of the illness being sixty-eight days—that is, from the beginning till the temperature settled steadily down to the normal.

Miss C——, aged twenty-six, fairly well nourished, rather anæmic, menstrual function normal. Gouty family history. No history of rheumatic fever or rheumatism. Was seen first on Oct. 9th, 1886. Had complained of some pain in the back and chest for the previous week. She was coiled up in bed in extreme pain, which was referred to the region of the left kidney, with excessive tenderness on pressure. Pulse 80; tongue clean; temperature normal; urine cloudy, containing copious lithates, but no albumen. A morphia and ether mixture was given, with chloroform and opium applied externally.

Oct. 10th (second morning).—Still in great pain, which now seems to shoot from the original seat up the back to the left shoulder, with very anxious look; complexion dusky; pulse 109; temperature 103°; a distinct direct murmur heard at the second interspaces; some tenderness all over the abdomen; tongue coated with smooth white fur; thirst; no headache or nausea. Evening (7 P.M.): In much the same state; temperature 101·5°; pulse 100. Ordered salicylate of soda, in ten-grain doses, every two hours.

11th (third day).—Temperature 104°; pulse 110; pain less; very restless night; some delirium; urine contained traces of albumen (sp. gr. 1020); systolic murmur heard up into the neck, rasping in character. Evening temperature 101·6°; pulse 120, and very feeble. Brandy given and salicylate discontinued; quinine in four-grain doses to be given every three hours. Bowels had acted; motions natural in character. An Austin's inhaler with carbolate of iodine is now to be used frequently.

12th (fourth day).—Temperature 102°; pulse 106. Some delirium in the night; severe headache; no nausea; pupils react to light.

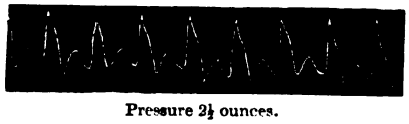
13th (fifth day).—Temperature 105°; pulse 120; respiration 28; headache; some delirium. Lungs carefully examined; nothing abnormal. Evening temperature 101°; pulse 110.

14th (sixth day).—Temperature 102°; breathing very shallow; respiration 28; constrictive pain round lower part of chest. Urine and fæces passed involuntarily. Evening temperature 103°; a roseolous rash observed on abdomen.

15th (seventh day).—Morning temperature 101°; some sickness, delirium, and headache; urine albuminous; sp. gr. 1018. As there is great difficulty in using the inhaler, an oro-nasal one was now substituted, with sponge saturated

[1] Abstract of a paper read before the Norwich Medico-Chirurgical Society.

Digitized by Google



with carbolic acid, creasote, and iodine. There is pain over the heart and distinct cardiac distress.

16th (eighth day).—Temperature 101°; almost constant, rather noisy, delirium in night; breathing shallow; respiration 30; moist râles heard over both bases; pain and tenderness over kidney, spleen, and liver; aortic systolic murmur, harsh and grating, heard all over chest. Seen by Dr. Bateman of Norwich. Quinine continued; small dose of grey powder; six ounces of brandy in twenty-four hours to be taken.

17th (ninth day).—Temperature 101°; very delirious in night, severe headache; passed evacuations involuntarily; pain, tenderness, and some enlargement of spleen; moist râles, with distinct creaking sounds heard at both bases; aortic murmur harsh; other sounds murmurish; pulse tracing dicrotous and feeble; slight jaundice.

19th (eleventh day).—Temperature 100·5°; headache less; better night; tongue fairly clean; takes nourishment well. Evening temperature 102·8°.

23rd (fifteenth day).—A slight rigor had been noticed in the night for the first time. Temperature 104°; pulse 120; respiration 30; headache and delirium. Called in the night, as she was thought to be dying. Temperature 102·6°; pulse 120, very feeble. (See pulse tracing.) Tincture of digi-

Pressure 2½ ounces.

talis in three-minim doses was given every two hours, and brandy increased to eight ounces in twenty-four hours.

24th (sixteenth day).—Temperature 103°; feels rather better: headache less; pulse tracing better. Evening temperature 101·6°.

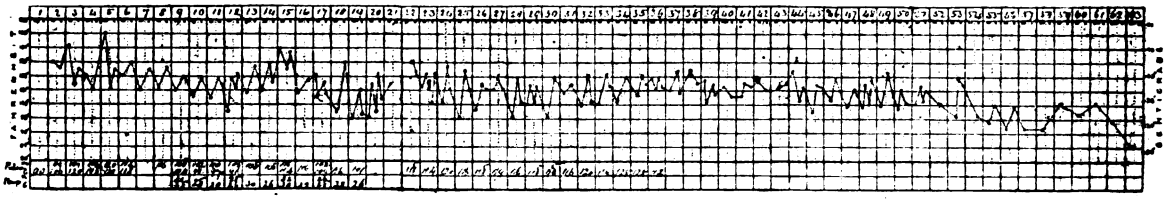
25th (seventeenth day).—Temperature 100·6°; pulse 109; respiration 29. Better night. A copious deposit of uric acid sand in urine, with trace of albumen. Cardiac murmur is decidedly softer in character; moist râles and creaking sounds heard over back and sides; a deep inspiration causes severe constrictive pain across lower part of chest; pain and tenderness over left kidney; tenderness over liver and spleen; bowels acting regularly; tongue almost clean; takes food well; still some yellow tinging of conjunctivæ.

30th (twenty-second day).—Slight rigor in night. Temperature 103°; tenderness over heart, liver, spleen, and leftp kidney; still some jaundice; condition of lungs and heart the same. Small doses of solution of perchloride of mercury, with ammonia and cinchona, given.

Nov. 6th (twenty-ninth day).—Temperature 100·1°. No headache; no delirium; jaundice almost gone. Condition of heart and lungs the same. A full inspiration still causes pain; tenderness over heart, liver, spleen, and kidney continues. Urine free from albumen; still some uric acid sand.

12th (thirty-fifth day). — Evening temperature 102·4°; pulse 125; tracing of exceedingly low tension; feeling of faintness on slightest movement. Brandy increased; tincture of digitalis in five-minim doses, with cinchona given every three hours.

13th (thirty-sixth day).—Pulse rather better; physical signs the same.



21st (forty-fourth day).—Slight rigor. Temperature 102·5°.

22nd (forty-fifth day). — The cardiac murmur was observed to be much softer in character.

For several days there was some nausea and sickness. The digitalis was discontinued, and bismuth and soda given.

On Dec. 3rd (fifty-sixth day), the morning temperature was 98·8°, and the patient felt decidedly better. The lungs were free from abnormal sounds.

9th (sixty-second day).—Morning temperature 100°. From this time the temperature remained normal till the 16th, when it rose to 100°, and it has since remained normal. (See temperature chart.)

A condition of rather obstinate constipation was the only troublesome after-symptom I had to deal with. There was a steady but slow gain of strength from day to day. She got up for the first time on Jan. 4th. A brownish staining has replaced the roseolous rash. A deep inspiration still causes pain referred to the lower part of the chest in front. There is some slight tenderness over the liver, spleen, and kidney. A soft blowing systolic murmur is still heard propagated along the course of the larger vessels. Other heart sounds normal; still some tenderness on pressure in cardiac region. Has gained flesh; takes food well.

Remarks.—The recognition of ulcerative endocarditis as a distinct disease is comparatively recent. According to Osler[2] it occurs under three conditions: 1. As a primary disease affecting the lining membrane of the heart or its valves, either attacking persons in previously good health, or more often attacking the debilitated or those with old valve lesions. 2. As an associated condition in connexion with such diseases as rheumatic fever, pneumonia, scarlet fever, diphtheria, ague, &c. 3. An associated condition in septic processes, traumatic or puerperal. I consider this case a typical one of the disease beginning at the heart. There was no evidence of any previous heart lesion; the fever was secondary to the presumed renal embolism. The main diagnostic points are: 1. The endocardial murmur, its changing character during the illness, and its total disappearance. 2. The character of the fever as indicated by the thermometer, its irregularity of type, the exclusion of other affections—as rheumatic fever, pneumonia, &c. 3. The albuminuria, roseolous rash, jaundice, and the presumptive evidence of infarcts in kidney, spleen, and lungs. There was no initial rigor observed, and only three slight ones during the illness; there was no cough till the last week, and that was transitory in character. There was no irregularity of pulse observed, and no hæmaturia.

The disease is considered to be due to the presence of a micro-organism — the staphylococcus. These microbes exist in colonies on the endocardium, are swept into the blood current, lighting up a septic fever, and are found in the plugs of the vessels of the spleen and kidney. From what I have gathered from the literature of the subject, the prognosis is gloomy in the extreme. Almost all the recent authorities state that there has not yet been one recorded case of recovery, but admitting the anatomical possibility of it.

As to the treatment. Believing the disease due to the presence of a micro-organism, and a micro-organism of low vitality, the germinating power of whose spores is completely checked by a solution of 1 in 300,000 of bichloride of mercury, a rational method of treatment would seem to be to expose the blood to the action of an antiseptic vapour, which we can do by means of inhalations. This method of treatment was suggested to me by the following case.

June 2nd, 1882.—J. B——, aged twenty, first seen on this date, had been ill for about ten days under Dr. Stovin—an undefined illness: some dysenteric symptoms, with obscure pains in muscles and joints; slight fever; was able to walk about his room.

3rd.—Confined to bed. Temperature 102°. Some cough, with difficulty in breathing; a well-marked mitral systolic murmur heard at apex for the first time. For a few days in much the same state. There was a good deal of nausea and sickness.

About June 8th a well-marked phlegmasia alba dolens developed in the left leg. Cough much worse; some dulness at base of left lung; extreme fetor of breath, with profuse expectoration of extremely fetid greenish matter. We then determined to try antiseptic inhalations. An Austin's

[2] THE LANCET, vol. i., 1885.

Digitized by Google

inhaler was used with carbolate of iodine. In a very few days a marked improvement set in, the swelling of the leg was almost gone, the lung symptoms were decidedly better, and the fetor less; some broken down lung tissue was expectorated, the murmur at the apex still persisting. He went on steadily improving, and in about fourteen days was almost well. There was still some cough and expectoration, but no fetor. The cardiac murmur was softer in character. Before the end of August he was able to get out; cough gone, and the heart-sounds quite normal. I saw him a year after a perfect picture of health. The lung sounds were perfect, and the heart quite normal.

That this was a case of ulcerative endocarditis I have no doubt now, but at that time there was not much known on the subject by the ordinary general practitioner. Both Dr. Stovin and myself attributed his recovery to the inhalations, and, I think, rightly so, as amendment in all the symptoms began almost directly after using the inhaler.

In the December following this, Dr. Julius Pollock related a case of ulcerative endocarditis with pyæmic symptoms,[2] resulting in death on the fifteenth day. He says: "The treatment of ulcerative endocarditis with pyæmia is most unsatisfactory; none of the ordinary remedies had any real effect, nor did large doses of alcohol sensibly improve matters. I wish now I had tried the inhalation of carbolic acid or carbolate of iodine, and I would suggest giving such a line of treatment a fair trial in any case of the kind, especially where the lungs appear to be much affected." The case, I may say, was watched attentively throughout by Dr. Stovin (now of Stratford) and myself. I am sorry my notes are defective, but I think the main points and course of the case are correctly indicated. I have recently submitted them to Dr. Stovin for his verification.

In my recent case, though the inhalations were begun on the third day, I am afraid they were practically useless until the seventh day, when the oro-nasal inhaler was substituted. This was used throughout the illness for ten minutes at a time, about ten or twelve times in the twenty-four hours. I cannot help feeling that the gradual decline of the most urgent symptoms was due to the presence of the antiseptic in the blood, checking the growth and reproduction of the microbes, if not destroying them. The second indication in the treatment of my recent case was to keep up the failing power, and especially to combat the cardiac depression. Fortunately, nourishment was taken fairly well throughout (administered often), and consisted of strong broths, beef-tea, jellies, milk, eggs, &c. Stimulants were given freely when absolutely required. Digitalis, though often indicated, was given with caution, fearing to excite sickness or nausea; the sphygmograph was specially useful in giving the indication for it and recording its effects. During the most anxious part of the illness I was fortunate in having the co-operation and assistance of the young lady's brother, a very intelligent senior medical student, who watched the case most carefully, and to whom I am indebted for the minute records of the temperature. As he often heard the cardiac murmur during the illness, he tells me he auscultated the heart recently, and that the sounds seemed to him quite right; he could detect no murmur. This I can verify, as I saw my patient on March 26th; she was then able to walk a mile without fatigue. The heart sounds were normal and the lungs sound.

CASE OF ACUTE RHEUMATISM WITH HYPERPYREXIA.

By ARTHUR J. DALTON, L.R.C.P. Lond., M.R.C.S.

I READ with much interest Dr. Taylor's case of rheumatic hyperpyrexia in THE LANCET; and having had a very similar one lately in private, with even a higher temperature—viz., 108·6° in the axilla,—I venture to publish a few particulars of it.

Miss S——, aged twenty-four, never had rheumatism before, but her father, mother, and one sister had suffered from it on several occasions. On Dec. 31st the patient was seized with pains in the joints, which shortly became swollen and hot. On the fourth day she had a little pleurisy on the left side, with a good deal of pain. The temperature was never very high. On January 6th the pain in the joints disappeared, and an erythematous rash appeared over the body. The temperature now began to rise, and on the morning of Jan. 7th was 103°. Up to this date I had only seen the patient once, my partner, Mr. F. M. Miller, having been in attendance. In the afternoon of the same day, at 3.50 P.M., they sent round in a great hurry, and, Mr. Miller being out, I went at once to find the patient violently delirious, erythematous rash covering the body, pulse very feeble and not to be counted, and the temperature in the axilla 108·6°. I immediately ordered half an ounce of brandy with a little milk, which was given by the mouth with great difficulty. The patient was then stripped, and a sheet wrung out with ice-cold water applied to the chest and abdomen; also several lumps of ice, four or five in number, were placed outside the sheet. The patient was so violently delirious that it took three people to hold the ice on and keep her in bed. The sheet was replaced by another at short intervals and fresh ice applied.—4.5 P.M.: The brandy and milk, with a quantity of milk previously taken, was vomited, also a good deal of phlegm.—4.15 P.M.: Temperature 107·6°; pulse 160.—4.45 P.M.: Temperature 104°; pulse 124. Patient passing everything under her, and motions very much relaxed and offensive.—5 P.M.: Temperature 102·4°; pulse 124, weak. Patient now fairly conscious, but much hesitancy in speech and difficulty in finding words; good deal of muttering and trembling of lips. Subcutaneous injection of brandy (ten minims).—5.20 P.M.: Temperature 100·6°; pulse 128, stronger. Injection of brandy (fifteen minims) subcutaneously.—5.40 P.M.: Temperature 99·6°; pulse weak. The ice was now removed, patient dabbed dry, and put into another bed in the same room between blankets. She was now quiet and conscious.—6 P.M.: Temperature 97·2°. Injection of brandy (fifteen minims) repeated, and, as patient complained of feeling cold, a hot bottle was applied to the feet.—9.30 P.M.: Temperature 99°. Quite conscious and comfortable.—12 midnight: Temperature 102°; pulse good. Face a little flushed. Ice was applied to the head, and ten grains of sulphate of quinine were given in a little orange juice. The patient was given small quantities of brandy and milk during the night. The temperature taken through the night by patient's sister was as follows: at 1 A.M., 102°; 2 A.M., 103°; 3 A.M., 103°; 4 A.M., 102°; 5 A.M., 103°; 6 A.M., 103°; 7 A.M., 104°. The patient was also given five grains of sulphate of quinine every two hours.

On seeing the patient at 8 A.M. on January 8th, I found she had taken a pint of milk during the night, and about seven dessertspoonfuls of brandy. There had been no sickness. Her temperature was 103·3°, and pulse 120, full and regular; respiration 36. The patient complained of feeling tired, and seemed inclined to sleep. She had had a fair amount of sleep during the night, and had passed a large quantity of urine naturally, having passed nothing more under her.—11.40 A.M.: Temperature 101·8°; pulse 109; respiration 33. Since 8 A.M. has had six dessertspoonfuls of brandy with milk and quinine, five grains every two hours. She is now a little deaf, with some buzzing in ears, and very drowsy. No headache. Last quinine powder was vomited. The brandy and quinine to be discontinued.—4 P.M.: Temperature 101·6°; pulse 110; respiration 37. The breathing resembles Stokes' respiration. Since 12 o'clock has had no brandy, but has taken a pint of milk without sickness. Quinine (five grains) to be repeated. Ice still to head. The patient expresses herself as much better. The bowels have acted well; motions pale, but not relaxed.—9.15 P.M.: Temperature 101·5°; pulse 100; respiration 36. Has slept a good deal during the day. Takes plenty of milk. The quinine now to be given every four hours. The temperature during the night did not exceed 101·4°.

Jan. 9th.—10.30 A.M.: Temperature 100·8°; pulse 93; respiration 32, more regular and less noisy. Quinine given every six hours. No pain in any of the joints.—9.20 P.M.: Temperature 100·4°; pulse 92; respiration 32, quiet. This evening the patient says voices have been talking to her. Head has been a little uncomfortable. Since 5 P.M. has had a little pain in the left knee and ankle, also in the wrists, but there is no swelling or redness. Quinine to be discontinued, also ice to be removed from head. Both to be repeated if the temperature reaches 103°.

10th.—Breathing normal. No pain anywhere. Temperature through the day varying from 99° to 100°. The skin has resumed its normal appearance.

11th.—Temperature throughout the day 99°.

12th.—About 11 o'clock last night the pain in the wrists

[2] Ibid., Dec. 9th, 1882.

Digitized by Google

returned, and the temperature went up to 101°. This morning the patient has pain in the wrists and shoulders. Ordered ten grains of salicylate of soda every three hours.

13th.—Pain in shoulder still troublesome. Ordered ten grains of salicylate of soda every two hours. Temperature remains about 100°.

16th.—Pain gone from shoulder, which, however, is stiff and powerless. Temperature normal. Shoulder to be well rubbed with oil and worked frequently.

20th.—Temperature still normal. Patient now taking ferri et am. cit., &c. Shoulder improving.

23rd.—Patient got up for the first time. Shoulder still stiff. The after treatment consisted in keeping the shoulder well worked, and a mild preparation of iron taken internally.

On March 16th the patient was in her usual health and spirits. All stiffness had disappeared from the shoulder, she had had no return of pain anywhere, and it is satisfactory to state that there had been no cardiac trouble throughout. As in Dr. Taylor's case, the patient remembered nothing afterwards of the cold applications; neither did the temperature again rise to a dangerous height. All temperatures were taken in the axilla, and it was interesting to note as the temperature dropped the gradual transition from violent delirium to consciousness. I think in a subsequent case I should remove the ice and place the patient in blankets earlier than I did in the present one.

Bethune-road, Stamford Hill.

CASE OF ACUTE RHEUMATISM WITH HYPERPYREXIA,

SUCCESSFULLY TREATED WITH COLD BATHS, AND ICE-BAGS TO THE NAPE OF THE NECK.

BY WALTER GREENE, L.R.C.P., M.R.C.S. LOND.

A. B——, aged thirty-six, came under my care on January 18th, 1887. He was then suffering, he supposed, from the effects of a severe chill, and complained of pain in his limbs and some of his joints, and there was slight febrile disturbance. When seen three days later the temperature was 103° and the pulse 120. There was considerable pain and swelling of the wrists, finger joints, and ankles, and also profuse perspiration, having the characteristic rheumatic odour. I prescribed twenty grains of salicin to be taken every three hours, which was continued for a week, during which time the temperature was fluctuating, but rarely rose higher than 102°, and the joint complications and rheumatic perspirations continued. On the morning of the 28th (Friday) the temperature had risen to 103°, and there was much restlessness. The salicin in twenty-grain doses was then taken every two hours, but in the evening the temperature had risen to 103·6°. At 11 o'clock on the following morning (Saturday, January 29th) the temperature was 106°, the pulse 140 and irregular. Shortly after 12 o'clock the temperature had risen to 107·4°; the respirations were 43; the pulse was small, irregular, and uncountable; and there was lividity of the face and delirium. I now determined to try the effects of the bath. The only bath available was not long enough to admit of the patient's lying down in it; so he had to be supported in a sitting position, with the water, the temperature of which at first stood at 105°, up to his waist. I then poured cold water over his head, chest, shoulders, and back, from relays of cans and jugs which were kept in constant readiness, so as to afford a continuous supply, the nurse baling the warm water out of the bath as fast as the cold water was poured in. In about twenty minutes the temperature was brought down to 102°, and his mind appeared to be quite clear. He was then wrapped in a warm blanket and returned into bed. The temperature continued to decline, and in about a quarter of an hour after he had been replaced in bed it had fallen to 100·4°. A pericardial friction sound was now audible. In the evening the pyrexia was again increasing, and as so much relief had followed the former use of the bath, I determined if necessary to repeat it, and did so when the temperature reached 105°, having first given him an ounce of brandy. As he was very weak, I did not allow him to remain long; but had him wrapped in a warm blanket, and returned to bed as soon as the temperature had fallen to 103°. The bath, as before, was repeated at 3 o'clock in the morning (Sunday, 30th), the temperature having risen to 105°, and again at 11 o'clock, the temperature at this time having reached 106° (the same as on the previous morning at the same hour). After being replaced in bed, a bag of ice was now kept continually applied to the nape of the neck, and this I found by its occasional removal was exercising a markedly controlling influence upon the temperature, which did not again rise above 104°. The slight pericardial friction sound could still be heard. Towards evening he became very restless, and as he had passed several sleepless nights, I gave him, within half an hour of each other, two doses of thirty minims each of paraldehyde. This having no effect, I then gave him thirty grains of bromide of ammonium, and at the same time a subcutaneous injection of liquor somnifera, after which he had a few short intervals of sleep, lasting about one or two hours at a time. The following morning (Monday, the 31st), the temperature being 104°, I gave him twenty-grain powders of salicylate of soda every three hours. He took five, but the effect upon the temperature was insignificant. The extreme restlessness, or rather wakefulness, which had continued through the day, increased in the evening, and towards midnight he appeared to be sinking. He was unconscious, though lying apparently awake, with his eyes wide open. The pulse was exceedingly small, and quite uncountable; the respirations shallow, and 44 to the minute. I then injected over a drachm of ether subcutaneously, and gave him an ounce of brandy. A marked improvement in the pulse ensued, and consciousness returned. He was, however, still very restless, so I prescribed forty grains of urethan, which, although it did not induce sleep, seemed to improve the character of the pulse. I then injected three minims of liquor somnifera subcutaneously, and in about a quarter of an hour after this the respirations had fallen to 19 and the pulse to 108, and he slept quietly for two or three hours. On awakening, some milk was taken, and I again gave him forty grains of urethan, after which the general condition greatly improved, and he slept at intervals the greater part of Tuesday morning. During the following three days, although the patient was very prostrate, the temperature gradually fell, and a slight improvement was observable. There was, however, a tendency to nervous excitement, and I prescribed each night eighty grains of urethan, and injected subcutaneously three minims of liquor somnifera. The pericardial friction sound, first observed on the Sunday, was still audible, little or no liquid effusion having taken place. The pain and swelling of the joints gradually decreased. Each day some progress was made, and on Feb. 4th he was able to sit up, complaining only of great weakness and some stiffness in his joints. On the evening of Feb. 19th he appeared to be threatened with a relapse. His hands, wrists, and shoulder joints became swollen and painful; he was bathed in a profuse perspiration having the rheumatic odour; the temperature rose to 101·2°, and the pulse to 109, and in the night he complained of a sharp pain in the præcordial region. In addition to the quinine which he had been taking in five-grain doses twice daily from the time the temperature subsided, I now gave him twenty-grain doses of citrate of potash. These symptoms continued for about a week, and then gradually passed off, leaving him exceedingly weak and helpless. From this time, however, he slowly and steadily progressed towards recovery. It was a noteworthy feature in this case that when the temperature was rapidly rising, and while the hyperpyrexia continued the joint pains and acid perspirations entirely disappeared. At such times the skin was dry, and the patient seemed to move his limbs freely and without apparent discomfort.

Remarks.—This is his third attack of acute rheumatism, and the high temperature coupled with delirium, and the signs of a failing circulation, as indicated by the lividity of the surface and an almost imperceptible pulse, are sufficient to mark it as being one of the greatest severity. It presents points of great practical interest. Salicin and salicylate of soda failed to exercise their so-called specific action. From January 21st to 29th my patient had taken at least 1280 grains of salicin, and in spite of this the temperature had risen to 107·4°. No better result followed the administration of salicylate of soda, of which he took 100 grains, though in both instances the drugs were of excellent quality. The effect of cold baths in these extreme cases is well known and needs no comment, but the influence on the tempera-

Digitized by Google

ture exerted by the ice-bag at the nape of the neck, in close proximity to the heat-regulating centres, is worthy of notice. Urethan given in large doses, on some occasions as much as eighty grains at a time, had little or no influence in procuring sleep, though it sometimes seemed to allay the extreme restlessness, which was such a troublesome factor throughout this case. Its principal effect, however, appeared to be exerted in improving and steadying the pulse.

Wallingford, Berks.

BRIEF NOTES OF THREE CASES OF

INTESTINAL OBSTRUCTION ILLUSTRATING SOME POSSIBLE ERRORS OF DIAGNOSIS.

BY HAROLD G. TAYLOR, M.D. LOND.,
ASSISTANT MEDICAL OFFICER, ROYAL ALBERT ASYLUM, LANCASTER.

CASE 1. *Chronic intestinal obstruction simulating tabes mesenterica.*—W. M. T——, an imbecile boy aged sixteen, with family history of phthisis. Towards the end of August, 1882, it was noticed that he had fallen off a good deal in flesh, and had occasional attacks of abdominal pain and diarrhœa. On examination of the abdomen there was found to be general enlargement with prominence of the superficial veins, and apparently a little ascites. On Sept. 21st a tumour was felt in the right iliac region, which subsequently extended into the hypogastric region; it was hard, lobulated, and easily mapped out with the hand, being evidently distinct from the liver and kidney. The symptoms were gradual emaciation, abdominal pain, occasional vomiting (which, however, was never copious or uncontrollable), and a tendency to diarrhœa, the motions being of a dark muddy colour. The morning temperature was generally about normal; in the evening it was usually a little over 100°, but sometimes as high as 102°. He died on Oct. 31st without any fresh symptoms. The diagnosis made was tubercular disease of the mesenteric glands. The post-mortem examination showed that the cause of death was intestinal obstruction. The tumour felt during life consisted of coils of intestine closely matted together by peritoneal adhesions, and distended by a dense fæcal mass consisting almost entirely of potato parings.

CASE 2. *Acute intestinal obstruction simulating choleraic diarrhœa.*—S. B——, an imbecile boy aged sixteen, with feeble circulation and subject to occasional attacks of diarrhœa. On July 30th, 1883, some friends came to see him and gave him a good many sweets. The same night he had diarrhœa badly; the next day he looked very pale and ill; about noon the diarrhœa recurred, he became very blue, and his pulse was almost imperceptible. He was put to bed and stimulants administered; he looked better, but diarrhœa continued.—Aug. 1st: He was restless during the night, and the diarrhœa still continues; the stools are liquid, of a *dark-greenish mud colour;* he complains of no pain but is thirsty; the hands and feet are cold and the pulse imperceptible; temperature in the axilla 102°, no abdominal distension; tongue slightly coated; he has taken plenty of milk and beef-tea, *without sickness.* Ordered a mixture containing tincture of opium, compound spirit of ammonia, spirit of chloroform, and tincture of catechu, every three hours, and two teaspoonfuls of brandy every two hours, with warmth to the surface by hot flannels and a hot-water bottle. He, however, did not rally, and died at 2.45 next morning. The post-mortem examination showed that death was due to intestinal obstruction, the seat of obstruction being the sigmoid flexure of the colon, which was tightly packed with hard scybala.

CASE 3. *Acute intestinal obstruction simulating choleraic diarrhœa.*—Arthur T——, an idiot boy aged fifteen. Aug. 17th, 1886: The last fortnight he has been suffering from disordered bowels, apparently diarrhœa, the motions being liquid and of a dark-green colour (according to the nurse). During this time he has been sick twice, and has not taken his food as well as usual. This morning the symptoms suddenly became more acute, he vomited repeatedly during the day, and there was an almost constant liquid flux from the bowels. Towards evening he became very much exhausted, the pulse being quick and feeble and the hands and feet cold. Stimulants, astringents, and sedatives were administered freely without effect.—18th: This morning, at 8 o'clock, he looks very bad; he is hollow eyed, the surface is cold and clammy, and there is no pulse perceptible. He has been sick only once during the night, but there is almost constant retching, and the diarrhœa has continued almost incessantly, the stools being liquid and of a peculiar *muddy* colour. The character of the stools called to mind the previous case; the rectum was therefore examined with the finger, and just at its tip a hardened mass of fæces was felt in the upper part of the rectum. An attempt was made to break it down, and then a copious enema was administered. Nothing came away immediately, but about two hours afterwards a piece of slate pencil 2½ in. long was extracted from the rectum with the finger; subsequently, after repeated enemata, a quantity of small pieces of slate pencil about an inch long, a few bits of stick, some pieces of rag, and fragments of wool, came away. All the bad symptoms passed off, and the boy rapidly recovered.

BULLET WOUND OF SPINE; PARALYSIS; SECONDARY ABSCESSES; DEATH.

BY JUSTYN GEO. D. DOUGLAS, M.D., C.M.,
HONORARY SURGEON, BOURNEMOUTH COTTAGE HOSPITAL, ETC.

BULLET wounds occurring in civil practice are comparatively rare, and the records of any case are always of sufficient interest to merit their publication. The following notes of a recent tragical case that has happened in a quiet seaside town, presenting some unique features, will probably be deserving of perusal.

Walter W——, aged forty-four years, a gentleman of independent means, following no profession, when on a visit to Bournemouth, went out for a walk on the Common near Westbourne, between 4 and 5 o'clock on the afternoon of Sept. 11th, 1886. He overtook and passed a man walking in the same direction, who was going more slowly and who appeared to be lame. After getting some five or six yards beyond him, he was suddenly shot in the back and fell to the ground, the man firing two other shots at him from a revolver. Assistance being rapidly procured, the assailant was secured and Mr. W—— carefully conveyed to the Bournemouth Cottage Hospital, where he was temporarily attended by Dr. Snow (in the absence of myself and the other surgeons), who found him conscious, but in a state of collapse, complaining of pain in the back, numbness, and inability to move his legs freely. At 8 P.M., an examination of the wound showed a small circular opening about the level of the tenth dorsal vertebra, a little to the left of the mesial line of the spine. A probe was carefully passed down for about an inch and a half, but no bullet could be felt; there was some œdema round the wound and oozing of blood. There was found to be slight movement in the legs, but sensation was impaired, especially in the calves of the legs and dorsum of the feet. The right ear had been penetrated by a bullet, there being a small circular opening through the concha. As the patient was still suffering from shock, further examination was not deemed advisable. A pledget of lint dipped in carbolic oil was applied to the wound and some ice put over the part. Two ten-minim doses of tincture of opium had been administered at 6 and 7 P.M., and as there was still a good deal of pain over the lower part of the back and abdomen, twenty minims of tincture of opium were ordered at 9.30 P.M. The patient could not pass his urine. There was no vomiting, and he took a few ounces of Liebig's beef-tea.

Sept. 12th.—The patient passed a bad night, suffering from a good deal of pain and restlessness; one-sixth of a grain of morphia, given hypodermically about noon, afforded great relief. Owing to the serious nature of the case, his depositions were taken before a magistrate, who attended in the afternoon. About an ounce of clear urine was voided. Temperature in the morning 99·6°; evening 100·6°. Pulse in the morning 88; evening 108.

13th.—Quiet night after two hypodermic injections of morphia. Twenty-nine ounces of urine drawn off in the morning, very bloody, probably from kidneys. Bowels confined; two enemata, which were used to empty them, were not retained owing to the relaxed condition of the sphincter. Temperature, 100·2°; pulse, 108. Mr. Victor Horsley came down this evening and examined the patient. After consultation, it was considered that there was no local evidence of injury to the spinal cord itself; the partial loss of movements in the legs and the impaired sensation

Digitized by Google

were attributed more to concussion of the spinal cord than to direct injury to it. Vastus reflex present, cremasteric absent; superficial reflexes over the chest and abdomen well marked. Some pain on pressure to the right of the umbilicus felt in the leg, also on pressure on the right side of the scrotum. Crural branch of genito-crural nerve, also genital branch on the right side in line, and this pointed to pressure on the right genito-crural, and also, probably, on the right external cutaneous. The bullet probably pierced the body of the vertebra from left to right and lodged in the right psoas. The danger was, of course, septic mischief, but an attempt to extract the bullet was agreed upon.

14th.—Passed a quiet night. At 8 A.M. the urine was drawn off and found to be quite clear. The following operation was performed by Mr. Horsley. Chloroform having been given, an incision was made down the middle line of the body, beginning at the wound of entrance made by the bullet and extending down about five inches in length, and another incision was made at right angles to it, running to the left for about two inches. The track of the bullet was followed downwards to the first lumbar vertebra, and it then appeared to pass between the transverse processes of the twelfth dorsal and first lumbar vertebræ; one of these transverse processes was removed by bone pliers, but the bullet could not be found or felt by exploring with probe or otherwise. No further attempt was considered either advisable or safe. The track of the bullet was then scraped with a sharp spoon, and the bruised tissues around the entrance wound were cut out, to place the entire track in as antiseptic a condition as possible. A solution of chloride of zinc (forty grains to the ounce) was used to cleanse out the wound, which was then sewn up and dressed carefully with carbolic gauze after the introduction of two drainage tubes. Full antiseptic precautions were adopted strictly throughout the operation, which was performed under the spray of carbolic acid.

15th.—Wound dressed under antiseptic precautions; looked well. Free discharge. Urine drawn off morning and evening. Bowels relieved by an aperient of mist. sennæ co. and decoct. aloes co. (of each one ounce). On testing the legs, the patient can move the right over the left, but cannot move the left over the right. Tactile sensation normal in right foot and leg, but impaired in left and absent from dorsum of foot.

16th.—Progressing favourably. Hypodermic injection of morphia continued as before. Bladder still requires use of catheter to relieve it.

17th.—Wound dressed. Small amount of serous discharge quite sweet. Sensation in left leg still diminished, and he complains of "pins and needles" in foot, also that he cannot keep the legs apart. Urine tested; no albumen.

18th.—Some slight cystitis appeared to-day. Bladder washed out with boro-glyceride solution, one drachm to the pint.

19th.—Erythematous rash over chest and back and on legs, probably due to the carbolic acid dressing. Corrosive sublimate was therefore substituted.

22nd.—Took a little solid food to-day, and passed a little urine without catheter. Wound looking well and line of incision healed, though open at either end. Some of the stitches removed.

24th.—Going on well. Temperature for last week has been 99° in morning, 100° evening. Remaining stitches taken out as they were causing some irritation. Wound had not been dressed for three days.

25th.—Bedsore forming over right trochanter of femur. Rather more motion in legs, and sensation in left a little better.

28th.—Wound dressed and all healed, except at upper part, and this only superficial. Dressed with boracic ointment.

30th.—Catheter passed only once a day. Temperature has been half a degree lower; evening 99·6°.

Oct. 2nd. Rather more feverish to-day. Temperature 99·4°; in the morning 101·8°, probably due to small fibrous slough separating from the upper part of the wound.

3rd.—Still feverish. Morning temperature 99·8°; evening 102·2°.

6th.—Moved on stretcher to Lansdowne House. Complaining of some indigestion. Ordered twenty minims of compound bismuth mixture twice a day.

7th.—Restless night, and complaining of hot burning pain in legs. Temperature lower: morning 99·2°; evening 100·4°.

9th.—The last two nights have been better. Morphia has been continued. Bladder greatly improved, and only occasionally washed out. Still great want of power in legs, especially the left. Bowels confined. Ordered pulv. glycyrrhizæ co. (one drachm) at bedtime.

10th.—Bowels acted four times, with flatulence and griping. Two drachms of brandy in arrowroot given.

12th.—Seen by Dr. Snow, and following notes taken:—"No tenderness over abdomen, and sensation normal. On the right side, between the knee and ankle, sensation is a good deal impaired, especially on the inner side over the foot, as if touched with a hot iron, and it is bent down; cold objects feel warm. On the left side, sensation imperfect below middle of left leg; cold objects also feel warm. As regards motion, the right leg he can draw slightly up, with difficulty semi-flexing it; the left leg, on the other hand, he cannot move at all. Ordered acid. phosph. dil. (five minims) and inf. cascarill. (half an ounce) bis die ex aq. a. c.; hypodermic injection of morphia as before.

Oct. 15th.—Slight rigor towards noon, and temperature ran up from 99·2° in the morning to 104° in the afternoon. Some powders of antipyrin, ten grains in each, were ordered, one or half a one to be given every two hours till temperature falls. One powder was taken, and two halves at two hours' interval, and the temperature fell to 102·2° in the evening. Two drachms of brandy to be given with food as required.

16th.—Better. Only one half dose (five grains) of antipyrin given.

17th.—Bowels relieved by injection. Better; night temperature lower.

19th and 20th.—Two half powders of antipyrin given.

21st.—Some quinine added to acid mixture, and no antipyrin given.

22nd.—Bedsore over trochanter and sacrum extending. Very apthous mouth. Ordered six grains of nitrate of silver in one ounce of water to be applied frequently.

26th and 28th.—One or two tablespoonfuls of pus passed from the bowels: rectum examined, but nothing to be felt.

29th.—Paraldehyde (fifty minims) was substituted for the morphia, but did not answer, and he had a restless night. Abscess of small size, which had formed in the calf of the left leg, was opened.

31st.—Slight amount of pus in fæces to-day, which were also very fetid. Temperature has been lower last three evenings; since pus was passed it averages 99·6° morning, 100·6° evening.

Nov. 6th.—Was seen by Mr. Erichsen in consultation with Dr. Snow and myself. Mr. Erichsen remarked that the bullet had stopped in the vertebral column; if not, it must have gone through and wounded the viscera; it had not gone through, however, but, striking the spine nearer the mesial line than the articulation of the rib, was either arrested in the bony part of one of the vertebræ or may have dropped into the pelvis. No further surgical exploration was possible; prognosis very gloomy, owing to danger of septic poisoning primarily, and secondarily the paralysis, exhaustion, and bedsores.

29th.—Has kept on much the same, but slowly losing ground and emaciating. Bedsores have greatly extended, large dry sloughs have come away, and there is evidently communication from the sacrum to the trochanter. Aphthæ come and go in the mouth, greatly kept under by application of weak caustic solution, glycerine, and borax, and washing out the mouth with oxygen water. Fever has been persistent, but not markedly high, being between 99·8° and 100° in the morning and 101·6° or 101·8° in the evening. Tendon reflexes exaggerated on right side and blunt on left. There is a good deal of inversion of right thigh and leg, which are also œdematous.

Dec. 9th.—Certainly weaker the last ten days, and more emaciated. Bedsores have greatly extended, resembling more a dry form of gangrene; all the bones of the sacrum are exposed and skin greatly undermined, especially on the right side, where the probe runs down to the bedsore over the trochanter. Has been ordered stimulants more freely.

30th.—Patient greatly wasted and wandering in his talk, misplacing and forgetting words; has been able to do with less morphia. Pulse has latterly run up to between 120° and 130°, thready, and very weak. Morning temperature 100°; evening 102°.

Jan. 3rd, 1887.—Slight dulness over both lungs, especially the left, where there is also some crepitation. Tubular breathing.

Digitized by Google

4th.—Very weak; respiration 36; sight, speech, and hearing gone; lung condition the same.

Jan. 5th.—Unable to swallow; unconscious; sinking.

6th.—Died this morning.

Necropsy twenty hours after death.—Present, Drs. Snow and Douglas, Parrott and Cusse. Body greatly emaciated and lower legs œdematous. Large deep bedsores over sacrum and right trochanter, exposing bone. Brain and membranes healthy except some slight congestion. Pericardium contained about two drachms of fluid. Left auricle and ventricle, especially former, full of decolourised clot. Heart muscular, tissue quite healthy, and valves normal. Left lung slightly adherent at base, and between one and two ounces of fluid in the pleura. Some congestion at base, but pieces float. The right pleura contained also a little fluid, and there was slight congestion at base. Liver natural in size and on section. On exposing and raising the bowels, a large diffuse abscess was found extending from the base of the left kidney, permeating the left psoas and passing into the internal iliac muscle. The pus was of curdy character. There were numerous small multiple abscesses in both kidneys, especially the left; capsules of the kidneys were non-adherent. On raising the psoas muscle, part of the iliac bone was found bare. After a careful and prolonged search, the bullet was found completely embedded in the twelfth dorsal vertebra, and to such an extent had the bone been penetrated that the base of the bullet did not project at all. Its situation seemed to be anterior to the transverse process. The cord appeared to be pressed upon, though not penetrated by the foreign body. Small spiculæ of bone and pieces of cloth, which had been driven in, were afterwards detached. To the naked eye there was no apparent change in the appearance of the cord or its membranes.

Bournemouth.

A TABULAR STATEMENT OF SIXTY-FOUR CASES OF ABDOMINAL SECTION,

INCLUDING FORTY-FIVE COMPLETED OVARIOTOMIES; WITH REMARKS.

By C. J. CULLINGWORTH, M.D.,

PHYSICIAN TO ST. MARY'S HOSPITAL, MANCHESTER; PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY AT THE OWENS COLLEGE; VICE-PRESIDENT OF THE OBSTETRICAL SOCIETY OF LONDON.

(*Concluded from page 209.*)

In all my fatal cases of completed ovariotomy it is probable that septicæmia was the immediate cause of death. But in one case, that of a young woman of twenty-two, the pericardium was found universally adherent from old inflammation; and in another, that of a patient of sixty-four, there was mitral disease of old standing. How far these conditions contributed to the fatal result I am not prepared to say. In four of the fatal cases the disease proved to be of a malignant character. Three of these were examples of sarcoma. In the fourth the patient had been tapped no fewer than nine times, and probably, as a consequence of the escape on some of these occasions of the contents of the cyst into the peritoneal cavity, the peritoneum had become the seat of a vast mass of soft, semi-transparent, proliferating tissue, filling up the pelvis and embedding within it the ovaries, both of which were cystic.

With regard to the condition of the second ovary, my experience has been, I believe, somewhat exceptional. Certainly, the proportion of cases, in which there was sufficiently marked disease of the second ovary to necessitate its removal, has been greater in my practice than in that of my colleagues at St. Mary's. Of the forty-five cases in the table, the condition of the other ovary in seven cases is not recorded; in sixteen it was either normal or simply atrophic, and was left undisturbed; while in twenty-two it was removed. The reasons for removal were as follows: in fourteen cases the organ was more or less enlarged and cystic; in one it was enlarged and indurated; in two the second ovary was normal, but was removed on account of a broad ligament cyst in close contiguity with the ovary; in one case there were ordinary cystoma of one ovary and a dermoid cyst of the other; and in four cases both ovaries were the seat of advanced cystic sarcoma. In all the cases in which the second ovary was removed the indications for that step were clearly defined, and my colleagues fully concurred in its desirability.

On three occasions I have operated on pregnant women. In one of these cases gestation had advanced to five months. Convalescence progressed normally until the ninth day, when uterine contractions commenced, and the patient aborted without any ill result. In the other two cases, the patients had only advanced two months in pregnancy. One of these recovered very favourably from the operation, and went home, but fifteen weeks after the operation she miscarried, the age of the fœtus being apparently about five months. The third patient was operated upon last September. She made an excellent recovery, without interruption to her pregnancy.

When alluding to the condition of the second ovary, I stated that in four of my patients both ovaries were affected with cystic sarcoma. Two of these patients died in consequence of the operation; the other two recovered rapidly from the operation, but died within three or four months from recurrence of the disease within the abdomen. As I have said elsewhere, the surgical treatment of sarcoma seems utterly hopeless. One patient, in whom the growth had all the appearance of malignancy, completely falsified the forebodings, in which, I believe, everyone who witnessed the operation was a sharer. The case (No. 36 in the table) was that of a girl of twenty-two years, in whom a large abdominal tumour had formed with suspicious rapidity. The growth was semi-solid in its consistence. It had been punctured a few days before I saw it by means of a small trocar, but no fluid had escaped. On opening the abdomen the case looked desperate. The tumour was a large, thin-walled, multilocular cystoma, with intimate adhesions to the parietes, omentum, and intestine. The gelatinous contents had, to a certain extent, escaped through the aperture made by the trocar into the peritoneal cavity. The omentum was greatly thickened, and the peritoneum was studded with soft papillomatous growths. The wall of the tumour was so thin that it gave way wherever there were adhesions to be separated, and it was impossible to prevent the contents escaping in all directions into the peritoneal cavity. I feared that I should be unable to complete the operation. In any case, it seemed unlikely that the patient could recover, and even if she did, the character of the growth led one to fear a speedy return of the disease. With much difficulty I succeeded in removing the tumour, cleansed the peritoneal cavity as well as I could, put in a glass drainage tube, and closed the wound. I told the friends what I conceived to be the nature of the case, and explained how it was scarcely possible to hope for ultimate recovery. To my utter surprise the patient got well without a bad symptom. The temperature on the evening of the day of operation was 100° F.; after that it never exceeded the normal. It is now twelve months since the operation, and the girl is at her work in perfect health.

I do not propose to speak further of individual cases; the main particulars of each will be found in the tables. There are some points, however, in regard to the operation and after-treatment, about which I shall probably be expected to say a few words.

Up to the end of 1886, I continued to use the carbolic acid spray in my operations. Personally, I have never seen it do harm, and as my cases seemed to me to do well in proportion as the details of the antiseptic method were rigidly adhered to, I hesitated to abandon any part of a system to which I owed so much. I do not consider the spray essential, and, indeed, I have since dispensed with it; nevertheless, it had its use, if only by being an emphatic reminder to everyone in the room that the case was being dealt with on antiseptic principles.

Of much more consequence than the spray is the thorough purification of the hands, sponges, and instruments. For the hands I now always employ a solution of corrosive sublimate (1 in 1000). For the sponges and instruments I use a solution of carbolic acid, of the strength, in the former case, of one part in forty, in the latter of one part in twenty.

In every case in which there is reason to anticipate oozing from the site of adhesions or any accumulation of fluid in the peritoneal cavity, from whatever source, I use the glass drainage tube. In simple cases I prefer to do without it, because I can then leave the dressings undisturbed for several days—a point, in my opinion, of no little importance. It will be found, on reference to the table, that the drainage

Digitized by Google

tube was used in twenty-two out of the thirty-seven cases operated upon during the last seven years. That the fifteen cases in which no drainage was employed all recovered, while of the twenty-two in which it was used five died, affords no argument against the value of drainage, as it was only used in the more serious cases.

Both for tying the pedicle and for the deep sutures, I use carbolised silk. Where superficial sutures are required, I prefer silkworm gut, which I have found absolutely unirritating, and which I should use for the deeper sutures as well if it were not quite so fine. The dressings I usually employ are pads of sublimate wood wool enclosed in gauze; over these I place a thick layer of cotton wool, retaining the whole in position by means of a many-tailed flannel bandage. Where no drainage tube is used, I leave the dressings undisturbed usually until the sixth day, when I remove the deep sutures.

The nineteen cases of abdominal section in the second table require for the most part but few words of comment. Already, allusion has been made incidentally to the first four on the list, and they need not now be further referred to. The two nephrectomies, and the case (the first on record) of the removal of an impacted calculus from the lower end of the ureter, have been published in detail in various journals and Transactions. So also has case No. 5, where a large quantity of pus had accumulated between the layers of the abdominal wall from the bursting of an ovarian abscess. The Cæsarean operation (No. 19) is merely included here because it comes technically under the head of abdominal section. The case will be fully reported elsewhere. Of the rest, three (Nos. 6, 9, and 18), were cases of exploratory incision for abdominal tumour, where the nature of the swelling was doubtful. Two of these turned out to be uterine myomata. The third was a case of malignant disease of the liver and peritoneum, with ascites, where the diagnosis had been obscured by the matting together of the intestines against the posterior abdominal wall. In none of these was anything done beyond establishing the diagnosis, and removing ascitic fluid where present. The abdominal wound healed well in each case, and the patients were no worse for the operation.

In two cases of uterine myomata I have felt justified, owing to the excessive and uncontrollable hæmorrhage, in undertaking the operation for the removal of the uterine appendages. In case No. 14 the operation was a complete success. Although a slight metrostaxis continued for some months, there has been no hæmorrhage of any consequence since the operation. The tumour has decidedly shrunk in all its dimensions, and has become softer. The patient has recovered from her anæmia, and to a great extent regained her usual health. In the second case the operation was not completed. On opening the abdomen the contents of the pelvis were found to be so matted together from old peritonitis that the tubes and ovaries could neither be seen nor felt. I thereupon closed the wound before any mischief had been done. A case may be bad enough to justify a comparatively simple operation, such as removal of the healthy or non-adherent appendages, and yet may not be bad enough to justify an operation involving greater risk, such as removal of the appendages when they are firmly adherent to other viscera, and so distorted and displaced as to be even recognised with difficulty. The patient in question recovered from the operation, and, owing no doubt to the rest and care, left the hospital with her symptoms relieved and her general health much improved.

Five of the remaining cases form a group in which the abdomen was opened, not on account of the presence of an abdominal tumour, but of intra-pelvic disease of a chronic and more or less obscure character. In a paper read before the Lancashire and Cheshire branch of the British Medical Association, and published in the *British Medical Journal* of Jan. 30th, 1886, I formulated certain conditions which, in my opinion, justify exploration in these cases. They are briefly as follows:—(1) That there shall be present physical signs of actual disease, in the form of one or more circumscribed intra-pelvic swellings, which appear not to spring directly from the uterus; (2) that there shall exist persistent pain, which rest and other simple methods of treatment have failed to relieve, and sufficiently severe in character to disable the patient from following the ordinary occupation of her life; and (3) that the patient and her friends shall be made acquainted with the nature of the operation, and shall be willing to accept the risk. These conditions were, I believe, fulfilled in all five of my cases. Two of them (Nos. 11 and 12) were published in detail in the paper just referred to; in both, the patients made excellent recoveries. In the case marked No. 8 in the table, there was a solid immovable tumour in Douglas's pouch, pushing the uterus upwards and forwards so as to interfere with the functions of the bladder. I thought I could move the uterus independently of the tumour. It turned out that in this I was mistaken. The tumour was a subperitoneal myoma springing by a short pedicle from the posterior wall of the uterus, and incarcerated in the pelvis. It was extricated with some difficulty and removed, the stump of the pedicle being secured outside the wound by means of a Kœberlé's serre-nœud. The patient unfortunately died of septicæmia on the third day. I now think it would have been better practice to have contented myself with liberating the tumour from its position without removing it. Nothing is easier than to be wise after the event.

The next case (No. 13) was that of a patient who had for some years been worn out and almost entirely disabled by chronic pelvic peritonitis. There was a distinct tumour to be felt in the neighbourhood of the broad ligament, and the patient was eager for an operation. The risk was fully explained to her, and she deliberately accepted it. The contents of the pelvis were much matted, the right tube was distended with serum, and there were three cysts in the broad ligament. The cysts and the diseased tube were removed, and many of the adhesions separated. A fresh attack of peritonitis unfortunately supervened, and the patient died on the third day. I was greatly distressed at the loss of this case, as the patient had acted for several years as caretaker at my consulting-rooms, and was a most worthy, loyal, and devoted servant. Nevertheless, while I deplore the result of the operation, I cannot reproach myself for having undertaken it. The fifth and last case (No. 16) was somewhat similar in its character; happily, however, it was more successful. There was a history of long disablement from chronic pelvic peritonitis, and a small fixed intra-pelvic tumour could be felt to the right of the uterus. On opening the abdomen, the uterine appendages were found universally adherent. Both tubes were enormously thickened from chronic inflammation, and contained in their walls several cysts. The right ovary was enlarged and contained many cysts, the largest of which was filled with pus. I removed both ovaries and both tubes, and the patient is now strong and well. This was a typical case for exploratory operation; one cannot conceive that any other mode of treatment, however long continued, could possibly have been of any avail.

The work, of which I have here rendered an account, has for many years been one of the great interests of my life. It is therefore not surprising that I should feel tempted to refer to some other lessons I have learned from it; but I must refrain. I cannot conclude these remarks, however, without gratefully acknowledging the friendly help and counsel I have at all times received from my colleagues at St. Mary's Hospital, and especially from my senior colleague, Dr. Lloyd Roberts. It has been my good fortune to assist him in a large number of his operations, both public and private, as well as to have the advantage of his assistance in many of my own operations. But while each has thus benefited by the experience of the other, the fact that Dr. Roberts had already won a reputation as an ovariotomist when I undertook my first case makes me, in this respect, by far the greater debtor. I am much indebted, too, to the three gentlemen who have successively held the post of house surgeon at the hospital during the last nine years (Dr. Walter, Mr. Winterbottom, and Dr. Donald), for the careful manner in which my cases have been recorded, and particularly to our present house surgeon, Dr. Donald, for his help in preparing the tables. A word of acknowledgment is also due to the nurses, whose devotion to these operation cases is beyond all praise.

Some portions of the retrospect I have here laid before the profession amount to a confession of failure; other portions, fortunately, are a record of success. Had it not been so, it is just possible (such is the weakness of human nature) that not even the sense of responsibility, of which I spoke at the outset, would have sufficed to draw from me the story of my early failures.

THE anniversary dinner of St. Bartholomew's Hospital was held on the 27th ult., the treasurer, Sir Sydney H. Waterlow, Bart., presiding.

TWO KNEE CASES.

SERIOUS INJURY TO JOINT WITH IDIOPATHIC EROSION OF CARTILAGES; REPEATED ASPIRATION; RECOVERY. FRACTURE OF PATELLA, TREATED BY SILVER LIGATURE; RECOVERY.

BY LEIGHTON KESTEVEN, M.R.C.S.

CASE 1.—At the Brisbane racecourse on Nov. 10th, 1883, J. W——, squatter, riding his own horse in a Corinthian race, having the inside running, at the turn for home in a hot finish brought his knee in contact with the distance post. So great was the concussion that the post—which was six inches in diameter—was snapped off at the ground. His leg was thrown backwards over the horse's rump, and he was nearly unseated, but managed to recover and get his leg over again, and rode in fourth or fifth at the winning-post. He was lifted off his horse and taken to the jockeys' room, where I saw him within five minutes of the accident. The leg was very much swollen, and the knee appeared to have received serious injury. He was at once conveyed into town and I attended him at his hotel. On examination I came to the conclusion that there was no fracture, nor any extensive laceration of the ligaments; but that the synovial membrane was lacerated, and most probably the semilunar cartilages displaced, as he was in extreme pain, and the joint was evidently filling fast with fluid. Three hours later the knee was greatly distended, the synovial sac bulging on each side above the patella, and the patella floating. On pressing it down on to the condyles (which, owing to the great distension could with difficulty be done) a grating sensation was communicated of rough surfaces, indicating that the forcible impact of the patella on the condyles had denuded the apposed surfaces of both of some amount of their cartilage. The calf of the leg was bruised from the knee to the ankle, and distended with effused blood; cold cloths and ice were applied, and morphia administered hypodermically and by mouth.

Next day (11th), under chloroform, I opened the calf of the leg (using eucalyptus spray) by an incision four inches in length, and removed about ten ounces of clotted blood from a hæmatoma formed by the sheathes of the muscles, washed out the wound with ice-cold carbolic lotion, stitched it up, covered it with boric lint, and bandaged as tightly as I thought safe. I then aspirated the knee joint, and removed twelve ounces of what appeared to be almost pure blood, giving great and immediate relief to the patient. The leg was then put up on pillows, steadied with sandbags, and cold irrigation applied to the knee. The fluid drawn off on being examined under the microscope proved to be nearly pure blood, and contained tesselated epithelium and cartilage cells. It clotted shortly after exposure to air. The general constitutional disturbance was severe; he had passed a very bad night, and had been awakened each time he dozed off by jumping pains in the knee. The grating could be very easily felt on rolling the patella on the condyles after the fluid had been removed. The temperature was 104°F.; pulse 120; skin hot and dry. A mixture was ordered of opium, aconite, and acetate of ammonia in camphor water. A medical man called in consultation by the patient's friends considered the injuries too severe to admit of saving the leg, and recommended immediate amputation.

13th.—Two other medical men, in consultation, in view of the palpably serious nature of the injury to the cartilage of the joint, recommended that the leg should be put on a long splint, to obtain ankylosis of the knee joint, as the only means of saving the leg. This advice I declined to act on, and, taking the responsibility myself, I put it on a Mclntyre's splint, flexed, and applied ice-bags to the joint, slightly altering the angle—i.e., increasing or diminishing the flexion—three or four times daily. The pain is very severe, especially the spasms at night, and the joint very tender on pressure. Temperature 103·4°; pulse 110. Not much pain in calf, which has not been disturbed.

14th.—The knee appears as much distended as on the 11th. Palpitations; temperature 103°. Aspirated, removing thirteen ounces of dark-red fluid, which examination shows to be sero-sanguineous with tesselated epithelium, but no trace of pus corpuscles. Great relief of pain.

15th.—Temperature 102·5°; pulse 96. Passed a better night [illegible] about five hours' sleep.

16th.—[illegible] severe rigor this morning; and though the knee was not so distended or painful and the temperature was not raised, I considered it advisable to aspirate for diagnostic purposes, and drew off eight ounces of fluid, red, but lighter than the last. No trace of pus; fewer epithelia. Carbonate of ammonia, iodide of potassium, and bark ordered, and six ounces of whisky daily.

22nd.—Temperature 99°; pulse 80. Very little fluid accumulating. Wound in calf undressed, first time since the operation; quite healed by first intention.

25th.—Increase of pain in knee: passed a bad night, with jumping pain. Temperature 102°; pulse 100 and rather hard. Patient flushed and irritable. Aspirated, getting only two ounces of clear, serous fluid; no pus cells. Extract of belladonna ordered to knee. Previous mixture repeated.

26th.—Temperature 99·8°; pulse 92. Flushing and irritability disappeared. Pain much less.

Dec. 2nd.—Temperature and pulse normal. Applied oleate of mercury to knee. Grating sensation plain. Carbonate of ammonia and iodide mixture reordered.

12th.—Very much improved in general health, appetite good, and bowels regular. Very little tenderness on pressure on knee. Grating still perceptible, but less; no jumping pain, only aches slightly at night. Joint painted daily with tincture of iodine.

25th.—Convalescing rapidly. Pain quite gone. No swelling or signs of effusion, but tenderness on putting foot to ground. Grating almost inaudible. Splint taken off, and the leg put into Sayre's plaster-of-Paris bandages from hip to ankle.

30th.—Left for home. In plaster-of-Paris, and on crutches. Very little tenderness on standing; no grating perceptible.

He had the bandages off a fortnight after this, and was getting about freely a month afterwards. No stiffness was left in the knee, and he says that that leg is as sound and reliable as the other.

Remarks.—In summarising the points of this case I would give the reasons of my diagnosis and treatment. The hæmorrhage into the joint might have proceeded from lacerations of the capsular ligaments, but from the tension, the peculiar defined shape of the swelling, and the constant presence of tesselated epithelium and cartilage cells, I felt justified in locating its origin principally, if not entirely, in the erosion of cartilage and synovial membrance from the surfaces of the patella and condyles in contact. Besides which the grating was of too distinct a nature to be mistaken for anything but denuded bone, and too early a symptom to be taken for the crackling caused by organised bands of adhesions. The spasm and jumping pain during sleep are diagnostic of erosion or disintegration of cartilage, and the heat and tenderness of the joint and agony on movement of synovial mischief. The effusion being traumatic and so rapid and the pain of distension so great, I felt that early aspiration with careful antisepsis was indicated as imperative: first, for the relief of pain, and, secondly, for the removal of what was evidently effused blood; and to the success in obtaining those objects, by relieving the pressure on the synovial membrane and removing a possible source of decomposition, I attribute the obviation of suppuration. The value of the microscopic examination of the effused fluid as a means of diagnosis and guide to treatment was most apparent, and enabled me to watch the processes going on inside the joint as plainly as if I had been able to see into it. The appearance of the leg the day after the accident was seemingly hopeless—cut, bruised, and black from the thigh to the ankle,—and yet by the aid of the microscope I was able to make a favourable prognosis from the beginning, and act on it, to the result of saving a joint which might have been sacrificed to expediency. My reasons for declining to adopt the suggestion of the straight splint to procure a stiff knee were the excellent general health of the patient and the continued absence of pus in the effused fluid. I therefore ordered the limb to be moved at intervals on the splint from the first to prevent the organisation of the effused fluid into fibrous adhesions, the position of flexion being adopted as affording the maximum amount of relaxation of the joint.

In a similar case, if of an asthenic type and ill-nourished, it might be necessary to obtain ankylosis to obviate further mischief in the joint; but I very much doubt if there are many cases so asthenic that careful nursing and nutrition would not pull through any such risks. With means of diagnosis so simple and practicable, if utilised with due care and precaution and in time, many a joint might be saved that is at present sacrificed to the plan of treatment by immobility.

CASE 2.—On the railway, near Brisbane, on Nov. 20th, 1884, J. B——, aged twenty-four, signalman, slipped on the metals, and fell on his knee, fracturing his left patella. His right foot was a club-foot (talipes equinus) and very wea[illegible]

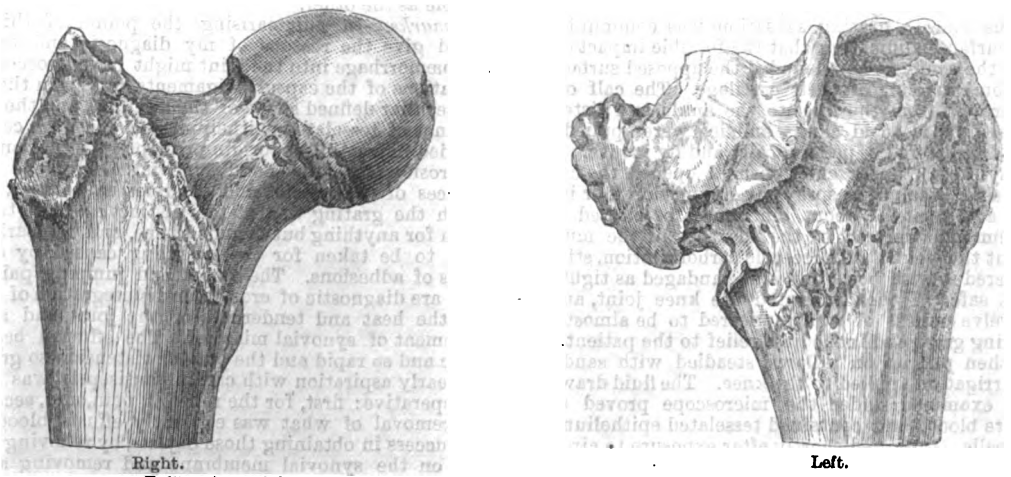
Digitized by Google

I had therefore no hesitation, in view of the very unreliable knee joint which a ligamentous union of the patella would give him (he being dependent on his own exertions for a livelihood), in deciding to ligature the fragments with silver wire. This I did on November 29th, under the eucalyptus spray. The bone drill snapped in one of the fragments, and I had hard work to get it out again. I hammered the ends of the wire into the patella. After ligaturing, the wound was stitched up, covered with a good pad of dry boric lint and oil silk, and bandaged. No drainage tube was put in. The temperature the following day was 99·5°F., and normal the day after, and continued so to the end. The wound was not undressed until Dec. 21st, twenty-two days after the operation, when the wound was found to be healed by first intention. Plaster-of-Paris bandages were then put on, and retained for three weeks. When removed, perfect union of the patella had taken place, and his leg was quite sound. Some day I think of taking the wire out or nipping the end off it, as it irritates the skin over it.

Remarks.—This case is useful—1st, as showing the great benefits this operation confers, compared to the old plan of ligamentous union. With a weak foot on one leg and an unreliable knee on the other, this man would have been incapable of earning his living; 2nd, as another added to the long list of successful ligatures of the patella for simple fracture. I was induced to send these two cases to you by the interesting nature of the "Occasional Records in the Science and Practice of Surgery," contributed to THE LANCET by Mr. Oliver Pemberton. The details of cases outside of hospital practice, treated by the operator himself throughout, with his reasons for such, may often very well be more interesting than the set notes by the surgical registrar or house-surgeon of another man's case.

Brisbane, Queensland.

OSSEOUS UNION OF INTRA-CAPSULAR FRACTURE OF THE FEMUR.

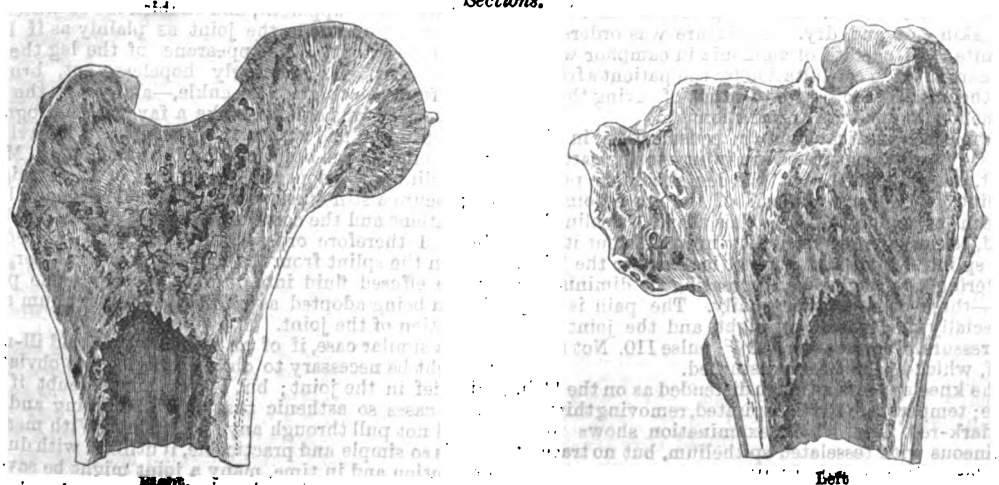


BY THOMAS F. RAVEN, L.R.C.P. &c.

A WOMAN, aged sixty-nine, slipped and fell, and on examination presented the usual symptoms of fracture of the neck of the femur, without impaction. She was treated with a long splint, and no extension was made. Her recovery was so rapid, and she walked so well subsequently, although with a shortened limb, that I was inclined to doubt the accuracy of my diagnosis, and to suspect that the fracture had occurred high up in the shaft. A short time ago she died, at the age of seventy-six, and I was enabled to secure the upper portion of each femur. The accompanying sketches, made with artistic fidelity by Mr. Arthur Trower, M.R.C.S., show how close to the head of the bone the fracture really was, and give a good idea of its complete bony union, and also of the contrast between the injured and uninjured bones, both in regard to the fracture itself and the resulting osteo-arthritis.

Sir James Paget tells me, after an inspection of the bones, that he does not remember to have seen so thorough a repair of this kind of fracture, and by his advice I have presented the specimens to the Royal College of Surgeons, where they will be found in the Pathological Museum.

Broadstairs.



Anterior Aspect.

Right. Left.

Bones removed from a woman, aged seventy-six years, who sustained a fracture of the neck of the left femur seven years previous to her death. The sketch shows strong bony union and erosions of the head of the bone from arthritis.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. BARTHOLOMEW'S HOSPITAL.

TWO CASES OF FRACTURE OF THE SPINE WITH DISPLACEMENT: IN ONE, DEATH AFTER RECURRENT ATTACKS OF ERYSIPELAS; IN THE OTHER, RECOVERY AFTER EXTENSION UNDER ANÆSTHETIC.

(Under the care of Mr. MORRANT BAKER.)

THESE two cases of fracture and displacement of the spine are of much interest. The first, in which there was fracture of the seventh cervical and first dorsal, with displacement of the cervical vertebræ forwards, is remarkable for the length of time that intervened between the infliction of the injury and the death of the patient. It is also interesting from the various morbid conditions which followed in the parts supplied by the cord below the damage. The second is an example of the value of extension when judiciously applied to displacements in the lumbar region, and somewhat resembles a case reported in THE LANCET (vol. ii. 1885, p. 114), where recovery followed the reduction of a displacement of the third lumbar vertebra. For the notes of the cases we are indebted to Mr. R. J. Reece, house surgeon.

CASE 1.—On June 17th, 1886, A. P——, aged eighteen, fell down a lift, a distance of forty feet. He was picked up and brought to the hospital, and admitted. It was found that he had sustained a fracture between the upper third and lower two-thirds of the left femur. He complained of no pain in the leg during manipulation, but of intense pain in his back and shoulders. He had a fracture of the spine about the first dorsal vertebra. Sensation in the hands and arms was retained, but there was loss of power. There was total loss of sensation below a line drawn transversely just below the nipples, the breathing being entirely diaphragmatic. Only very slight extension was required to bring the fractured femur into position, and it was not put up in splints, but kept in position with sand-bags.

June 20th.—The patient has vomited for the last day, but slept well last night, and takes large quantities of milk, with a little lime water. On examination it is observed that he has no power or sensation downwards from a line drawn round his chest three inches above the nipples, whereas on admission this line was situated half an inch below the nipples. The loss of power complained of in his arms and hands has increased, but sensation remains. Priapism, which all through has been very marked, being increased considerably on the passage of a catheter so much so, that a soft one was only passed with much difficulty,—is now present to a much more limited extent. Over the buttocks the skin is reddened, and threatens to break down, between the nates two large blebs being seen; glycerine and starch powder were applied. The left heel is also reddened; a circular cushion with a hole in the centre was placed under it, and under the nates.

The patient was placed upon a water-bed and the urine drawn off twice daily, the bladder washed out with Condy's fluid, and an ounce of solution containing one grain of sulphate of quinine injected and left in. Bowels open involuntarily. On inspiration chiefly, but also during expiration, from three to five spasmodic contractions of the muscles under the chin occur. Inspiration, as before, is entirely diaphragmatic, the chest walls falling in instead of expanding. He is able to cough slightly. There is apparently no dimness of vision; he can read a text on the opposite wall. Urine: sp. gr. 1010; acid; one-twentieth albumen; mucus.

June 26th.—Incontinence of urine setting in. Urine becoming offensive; sp. gr. 1008; trace of albumen; no sugar. Complains of pain in back and neck. Relieved by an ointment of cocaine, 5 per cent. in lard. Takes food well. Much thirst. Bowels open freely.

July 2nd.—Has a bedsore on the right elbow. Urine not so offensive as before; neutral; no sugar or pus-corpuscles.

19th.—Two or three small sores forming on buttocks.

25th.—Bedsores over posterior superior angles of ilia, the sacrum, and spines of scapulæ. They are painted with collodion. Appetite not so good.

Aug. 2nd.—Condition much better. Urine no longer offensive. Only one bedsore over left elbow, which is dressed with zinc lotion. Patient can move his arms better. Temperature, which has been raised sometimes to 102°, is now 98°.

23rd.—A bedsore forming over left heel. There appears to be firm union of the fractured femur.

26th.—Electrical examination: No line of hyperæsthesia; in the right arm electro-sensibility impaired. In the extensor muscles of the forearm A.C.C. > C.C.C. In the flexors and interossei and abductor indicis the reaction is normal. All the muscles except the hypothenar react to faradism. In the left arm the same conditions hold, but the hypothenar muscles contract to faradism, and there is no galvanic reaction in the interossei.

Sept. 9th.—Some facial neuralgia.

27th.—General condition much the same. Appetite good. Feels comfortable. Can raise his body from the bed on his elbows; no power over abdominal muscles. Sensation accurate over second rib, indistinct over third, lost below that. There is considerable wasting of muscles of forearm and hand. The fractured femur has united, but there are two inches of shortening. Under the microscope the urine contained no pus-phosphates. Bladder treated as before.

Oct. 5th.—After the bladder is washed out, patient sweats profusely over his face, neck, and arms.

28th.—After his tea (5.30 P.M.) patient vomited. Temperature, taken at once, 103°. During the evening nausea continued, and at 8 P.M. the temperature was 105°. The patient has some expectoration of frothy mucus, not more than usual. Urine as usual. No fresh bedsores. Pulse 142; respiration 32. Sweating profusely. Complains of pain in the head.

29th.—Erysipelas spreading rapidly from sore on left heel, reaching the knee by midnight. Enlarged glands in left groin, with inflamed skin over them. Vomited. Some convulsive twitching of arms. Delirious. Temperature 105°.

30th.—Blush not advancing. Temperature 102·4°.

Nov. 1st.—In the right leg there is no ankle clonus, patellar or cremasteric reflex. The left leg not tried, but no superficial reflexes on the left side. Diarrhœa. Temperature 103°. Urine alkaline; no albumen or sugar. The patient suffers much from nausea and vomiting. Abdomen distended over region of stomach. Œsophageal tube passed, a great quantity of gas escaping from the stomach, after which the patient was more comfortable and vomiting ceased. A bedsore forming on right thigh.

8th.—Respiration 28. Nausea. Desire to expectorate, but inability to do so. A fresh attack of erysipelas spreading from glands in groin.

10th.—Temperature normal. A fresh ulcer commencing on dorsum of left foot.

16th.—Two fresh ulcers forming on left foot. The patient complains of toothache.

17th.—Rigor. Temperature 104·2°. Vomited four or five times.

20th.—Temperature has been high since the 17th, once reaching 105·6°; to-day normal. Vomiting, which has been continuous notwithstanding the means taken to check it, is not so constant. There has been a blush on outer side of left thigh.

26th.—General condition much better.

Dec. 1st.—Patient carefully examined to-day. When the soles of the feet were tickled there were distinct contractions of the toes on the right foot, the outer toes twitching most; on the left the twitching was most marked in the big toe. There was no clonus of the ankle joint on either side. The patellar reflex on both sides was absent, nor was there any pectoral reflex. Sensation remains much the same, lower border of the second rib. While being dressed patient complains of severe itching sensation over the upper part of his chest (limited in area below by the lower border of the second rib) and neck. This he has always complained of, but for the last week or so it seems to be more intense. He describes it as if needles were running into him. On these occasions he perspires very profusely all over his face, neck, shoulders, and arms. The portion of his chest just below the line of sensation is also

Digitized by Google

covered with perspiration. This extends three or four inches down his chest, gradually dying away. His neck and the upper part of his chest, too, are at the same time covered with a bright red rash, and sometimes, slightly, the face. This rarely extends to the arms. To-day the rash not only covered the area of sensation, but extended all over the front and sides of the thorax, dying away over the abdomen. The pricking sensation passes away very quickly after the bladder is washed out, rarely lasting more than five or six minutes after the operation. The rash remains longer, gradually fading away in from a quarter to half an hour. The patient states that he sometimes suffers in this way, even when he is not dressed, or without any other known cause. On some days, except after dressing, he is free from it, while on others he has it two or three times during the course of the day, and also at nights. The left heel and foot are still ulcerated.

7th.—Bedsores increasing in size; still occasional vomiting and mucous expectoration.

13th.—Patient has increasing distress owing to inability to expectorate, the cough being extremely feeble. Sores all healing.

23rd.—Fresh bedsore over left buttock; iodoform used.

24th—Patient delirious for twenty-four hours, calling out loudly at night. Iodoform discontinued and sores poulticed.

Jan. 5th.—Abscess forming in left thigh; sores on right heel closed, but there is still one on the dorsum of the left foot.

7th.—An abscess of the left thigh burst, about two pints of rather fetid pus escaping.

17th.—The terminal phalanges of the little and ring fingers of right hand are necrosing. The nails are blackened and misshapen; beyond and towards the hand the skin is tense, red, and angry as far as the terminal phalanx. The abscess in left thigh discharges less and is much less offensive. All sores doing well. Much difficulty in breathing, and occasional twitching of muscles about neck and face.

19th.—Complains of toothache; tooth extracted without much pain; immediately after an ounce of brandy had been administered the toothache ceased.

20th.—The tongue is ulcerated and swollen. The whole of the bed is shaken by the attempts of the patient to breathe.

22nd.—A fresh attack of erysipelas broke out in the right leg, and he died on the 26th.

At the post-mortem examination, held twenty-five hours after death, the articular processes of the seventh cervical and first dorsal vertebræ were found to have been fractured, and the cervical vertebræ had been displaced forwards. Opposite the seat of displacement the spinal cord had been crushed within the dura mater.

CASE 2.—J. H——, aged twenty-eight, a ship's steward, was admitted on Nov. 22nd, 1886, under the care of Mr. Morrant Baker, suffering from a fracture and dislocation of the spine. The patient, from the age of fifteen, has been subject to epileptic fits, and whilst about to enter a train at a railway station he was seized with a fit, and fell between the train and the platform. On regaining consciousness he found he had lost power in the left leg, and was brought to the hospital.

His condition on admission was as follows. At the junction of the twelfth dorsal and first lumbar vertebræ there was an obvious displacement — the lumbar vertebræ being depressed, leaving the dorsal prominent. There was entire loss of motion and impairment of sensation in the left leg. There was hyperæsthesia in the right leg, with acute pain over an area corresponding to the distribution of the twelfth dorsal nerve. There was no bruising over the seat of injury.

The patient was put under the influence of ether, and, under the superintendence of Mr. Bruce Clarke, extension was made from the arms above the head and the ankles, the patient lying on his left side. The bones were seen to go back into position, but the displacement returned when the tension was discontinued. Extension was again applied, and maintained while the patient was placed upon his back, the vertebræ this time remaining in position. While making the extension, crepitus was distinctly felt by the hand placed over the seat of fracture. An extension of 5 lb. was applied to each leg, counter-extension being obtained by raising the foot of the bed. There was no hyperæsthesia in the right leg when the patient had recovered from the anæsthetic, and there was less pain at the seat of fracture.

Nov. 23rd.—No urine has been voided since admission. A catheter was passed and twelve ounces of urine drawn off; sp. gr. 1020; acid; no albumen; bowels acting normally.

24th.—To prevent any displacement of the spine occurring during a fit, the man was put into a plaster-of-Paris jacket extending from the axilla to below the trochanters. The jacket was previously prepared, commencing with a many-tailed flannel bandage, followed by numerous strips of crinoline bandage soaked in a mixture of plaster-of-Paris and gum, and internally a thick layer of wool. The gum was used to prevent the case setting too quickly. The jacket was placed upon a second bed, to the foot of which the patient's bed being brought, he was carried over the head of his bed and laid upon the jacket and enveloped in it. Extension being maintained during the time. There has been great pain of a spasmodic character down the course of the great sciatic nerve, followed by involuntary expulsion of fæces. As the rectum was distended, enemata were administered with marked relief. The urine was drawn off daily and the bladder washed out with a solution of Condy's fluid and an ounce of a solution containing one grain of sulphate of quinine injected and left in. The urine only occasionally had an alkaline reaction, and once or twice contained pus. Fifteen grains of benzoate of ammonia were given three times a day.

25th.—Patient has sensation over the anterior crural nerve, but not over the external cutaneous of the left thigh.

27th.—He can move the ankle joint and foot, and localise sensation better.

Dec. 11th.—Plaster jacket removed, and a poroplastic jacket substituted. The extension was removed a few days ago from the right leg, and to day from the left.

24th.—All muscles react to both currents normally, but the extension of the foot and the peroneal muscles react rather less easily than in the right leg, and the electro-sensibility is impaired to a slight degree below the knee.

18th.—The patient got up. He has very little power over the left leg, no control over his sphincter ani, and still uses a catheter, although several attempts have been made to dispense with it.

Feb. 4th.—Electric reaction of muscles of legs normal; power returning over the rectum; perineum galvanised (+ electrode).

8th.—During an epileptic fit urine was voided spontaneously.

15th.—The patient left the hospital. He had control over his rectum, but still used a catheter; could walk easily and without pain. The bladder had not been washed out for a month, the urine remaining acid. He complains of pain on pressure over the seat of fracture, and the last dorsal vertebræ are slightly more prominent than natural. Temperature, pulse, and respiration remained normal throughout.

CUMBERLAND INFIRMARY.

PERITONEAL ABSCESS DISCHARGING THROUGH THE UMBILICUS.

(Under the care of Mr. H. A. LEDIARD.)

THIS case seems to merit a little attention, on account of the doubt that was reasonably felt in satisfactorily tracing the suppuration to its origin, and the necessity there is of reading it in connexion with others where purulent discharge from the umbilicus has existed, in order to arrive at a correct conclusion as to the pathology.

The child's age was ten, and she was first seen on Feb. 3rd, 1886, having been brought to the out-patient room, a long distance, by her mother. For six weeks there had been swelling and tenderness of the abdomen. Her appearance was suggestive of the end of an exhaustive fever, which had rendered her exceedingly thin, weak, and haggard, for she lay in her mother's lap like a rag.

On admission the child's temperature was 100°, but for the next six days it was subnormal. In addition to a swollen abdomen with distended veins, the umbilicus was converted into a red, tender protuberance the size of a walnut, which burst a week after admission, the temperature rising to 103°; the discharge was very foul, but entirely purulent, and continued for a very long while, so long that it was thought that it might be needful to explore the abdomen.

On Feb. 18th a drainage tube was put into the peritoneum through the umbilicus, and although the temperature rose to 102° or 103° each night, the child began to improve. Examination of the abdomen suggested tubercular peritonitis to some who saw her in the ward, and this seemed confirmed by the fact that there were some moist sounds

Digitized by Google

heard in the chest. Mr. Lediard did not share this view, for when the child was admitted he could not help thinking of typhoid fever, and was somewhat supported in his first impression of the fact that whenever a long probe was passed through the sinus it always found its way to the region of the cæcum or towards the right iliac fossa. Occasionally it was thought that fluctuation was present, and a certain amount of thickening within the abdomen; but there was never any definite tumour to be felt. Pus could generally be forced, on pressure, from the umbilicus, whilst the smell was something more than simply foul.

In spite of a night temperature constantly more or less high, and profuse discharge from the sinus, the child picked up; in spite, also, of an always loose condition of the bowels, there being frequently three motions a day. The drainage tube inserted was about four inches in length in order to assist drainage. The child was made to lie on the stomach, but the change in position was not attended by any marked improvement. Tedious as the closure of the sinus was, yet the child's returning colour and ravenous appetite afforded a satisfactory sign that she was on the right track. It was not, however, until July 23rd that she was discharged well, with a good covering of flesh and in excellent spirits.

No good account of the child prior to admission was ever obtained, but what there was is consistent with typhoid fever. The record is epitomised as much as possible, but the temperature chart tells a great deal. Thus, on Feb. 27th and 28th the evening rise was 104°; on March 11th, 12th, and 13th it was 102°; on March 24th and 25th and April 5th it was 104°; the morning temperature being invariably subnormal or normal. In June lower variations were present, and towards the end of July the feverish symptoms had gone.

Remarks by Mr. LEDIARD.—Although the sequence of events cannot be considered as proved, I am of opinion that the child had typhoid fever, with ulceration of the bowel, perforation, and an intra-peritoneal abscess, which discharged itself through the umbilicus. The chest symptoms passed away very early, so that tubercular disease was eliminated from consideration. I heard during June of this year—that is, about a year since the child was last seen—that she was well and attending school. In looking for references to umbilical fistulæ, I find that Mr. Erichsen (8th ed., vol. ii., p. 857) states that they arise from perforation of the small intestine by chronic ulceration, usually tubercular, with the formation of a circumscribed abscess amongst the coils of the intestine, finally discharging at the umbilicus; but he makes no allusion to typhoid fever. West (5th ed., p. 117) mentions a case where from a quarter to half a pint of sero-purulent fluid escaped daily from the umbilicus of a child eight months old, the cause being peritonitis; also another case of acute peritonitis, where a puncture of a prominent umbilicus was followed by the discharge of forty-eight ounces of pus. Hilton Fagge (vol. ii., p. 248) says: "In some of those rare cases of strumous peritonitis in which the abdomen becomes distended with pus, the umbilicus gives way and allows the fluid to escape." Amongst the complications of typhoid mentioned by Fagge is peritonitis, which generally depends on a perforation of the bowel or sloughing of a swollen mesenteric gland, and he further quotes cases going to show that pus in the abdominal cavity is known as a sequel of the peritonitis of typhoid, due to perforation, which pus makes its way externally or into the bowel; he does not allude to the umbilicus as a mode of exit. In vol. xvii. of the Transactions of the Clinical Society of London, three cases of peritoneal abscess in children are recorded by Dr. Goodhart. The first case was a girl of eleven, and the symptoms and progress of the case are very similar to mine. The discharge had, however, no faecal fetor. The origin of the discharge was due to typhoid fever. The other two cases were treated by incision. From these few references it is clear that discharge [illegible] from the umbilicus may be tubercular, but is not necessarily so, and that, in the absence of evidence of [illegible] typhoid lesion will account for some of the other [illegible] peritonitis, in the form of a localised [illegible] through the umbilicus or elsewhere [illegible] of typhoid is obtained there [illegible] where a child makes so [illegible] which lasted for about [illegible] to be met with in tuber- [illegible] the abdomen usually con- [illegible], whilst the tube was retained [illegible] out of the sinus.

Reviews and Notices of Books.

An Introduction to the Study of Embryology. By ALFRED C. HADDON, M.A. Cantab., Professor of Zoology in the Royal College of Science, Dublin. With 190 Illustrations. Pp. 336. London: Charles Griffin. 1887.

THIS work is a condensation of our present knowledge of embryology intelligently arranged and well adapted for self-study, as the Germans express it. It is divided into eight chapters, which are thus occupied—1. The Maturation and Fertilisation of the Ovum. 2. Segmentation and Gastrulation. 3. Formation of the Mesoblast. 4. General Formation of the Body and Development of the Embryonic Appendages. 5. Organs derived from the Epiblast. 6. Organs derived from the Hypoblast. 7. Organs derived from the Mesoblast. 8. General Considerations. It is difficult, of course, rigidly to limit the description of the parts derived from the several layers of the blastoderm in compound organs—as, for example, in the case of the eye and ear; but upon the whole there is little overlapping, and these sense organs in particular are wholly given under the head of "Organs derived from the Epiblast." Mr. Haddon's qualifications for undertaking so important a work as the present are that he was engaged for a considerable period in working at development, especially of invertebrata, in Dohrn's Marine Biological Station at Naples, and has published one or two good memoirs on the subject. He has thrown himself thoroughly into his work, and seems to have exhausted all the literature of embryology since the date of Balfour's unfortunate death. Much interest is added to the details of development by suggestions as to the cause of the first appearance of the different organs. The reader will find remarkably good accounts of the different forms of placenta, of the development of the heart, and of the genito-urinary system, in which all recent work is included. We venture to give a short extract from the section on the placenta which will serve to show the mode in which Professor Haddon deals with his subject. After having described the allantois in the bird and the peculiarities of the chorion in the lower mammals, he goes on to say that the nature and position of the villi of the chorion vary considerably.

"The villi fit into depressions of crypts of the uterine wall, the conjoint structure being known as the placenta. The placenta of the Rodentia, Insectivora, and Chiroptera is usually dorsally situated and discoidal, as in the rabbit, and is coextensive with the area of contact between the allantois and the subzonal membrane. In these forms the yelk sac is in contact with the larger portion of the subzonal membrane. In Edentata the placenta may be discoidal (Loricata), or dome-shaped (Pilosa), or zonary (Tubuli-dentata)—that is, occupying a broad band round the chorion, leaving the ends free from villi, or diffuse (Squamata.) In the dog the large vascular yelk sac does not fuse with the subzonal membrane. The allantois first grows out on the dorsal side of the embryo, where, coalescing with the subzonal membrane, it forms (at first) a discoidal placenta. The villi soon extend, so as to form a zonary placenta. The zonary placenta is found in the carnivora, hyrax, and elephant. The extension of the placenta over the whole of the chorion results in what is termed a diffused placenta. This is characteristic of the Perissodactyla, the Simia, the Tragulina, the Tylopoda, the Sirenia, the Cetacea, and the Lemuroidea. The collection of the villi into groups constitutes what is known as a cotyledonary placenta. This variety is confined to the Pecora."

The mode of formation of the decidual and non-decidual placenta is then given, and finally an excellent *résumé* of the recent researches of Kupffer, Selenka, Hensen, Spee,

Digitized by Google

and Heape on the field mole, mouse, rat, guinea-pig, and mole. The illustrations are numerous and intelligible, and the work may be regarded as fairly representing the present state of embryological knowledge. It is handsomely got up, and has a very good index.

OUR LIBRARY TABLE.

On Holidays. By RODERICK MACLAREN, M.D. Edinburgh: Oliver and Boyd.—This is an address delivered by Dr. Maclaren in his capacity of president of the Carlisle Medical Society. The subject is one pecularly *apropos* to the present season, and it is handled with the facility and force of an experienced traveller. Dr. Maclaren lays it down as an axiom that "a considerable amount of contrast to ordinary life is an essential condition of a successful holiday. I would have the man who lives at the seaside go to the hills, the town man go to the country, the country man to the town; the man who leads an active stirring life should loaf, the sedentary man go for a walking tour." This is in the main sound, but the contrasts between ordinary life and holiday time must not be too severe. The sedentary brain-worker, with soft muscles and weak heart, should not propose to himself a month of severe mountain climbing, or a prolonged walking tour at the rate of thirty miles per diem. There are few commoner errors than to imagine that severe physical exercise is a panacea for an overwrought brain. Dr. Maclaren thinks that of all forms of holiday the Swiss tour is the best for the Englishman, as the contrast of climate thus secured is great, and the scenery is of unsurpassed magnificance. He advises tourists to Switzerland to make for the characteristic feature of the country—the snow mountains and glaciers,—and thinks that the bulk of the holiday should be spent in this region. Much useful and trustworthy information is given regarding mountain-climbing and glacier-walking. The writer regards these pleasures, when wisely ordered, as almost free from serious risk. For men past their prime, whose livers and kidneys are no longer so active as formerly, Dr. Maclaren recommends a holiday at a German spa. He thinks the sea voyage presents exceptional advantages for "men under middle age who are somewhat run down by mental work and worry, who are not fit for, or in need of, much exercise; secondly, for spare old men who are bad sleepers and have healthy livers." The writer concludes with the description of a tour to Tangier, borrowed from the note-book of a relative. Dr. Maclaren's own experience is so considerable that such extraneous aid was hardly necessary, and it does not add to the value of his *brochure*.

Health Resorts at Home and Abroad. By M. CHARTERIS, M.D. Second Edition. Pp. 212. London: J. and A. Churchill. 1887.—This edition differs from the first chiefly in the addition of Malvern to the English, Royat to the French, and Wildbad to the German watering places described, an account of the American health resorts of Saratoga and Richfield Springs, and a useful table giving the comparative analyses of groups of springs. The alphabetical list of health resorts has been considerably extended, and rearranged according to the countries in which they are situated, but the information afforded respecting them is meagre. Dr. Steinschneider's [illegible] is again issued with the book.

Vittel (Vosges, France): Medical, Picturesque, and Anecdotal. By PAUL RODET, M.D. Pp. 222. London: J. [illegible].—The object of this book is to bring [illegible] of the mineral waters of Vittel. This is of [illegible] formation, having been erected only in 1880. The [illegible] of the Grande Source closely resemble those of the Source du Pavillon at Contrexéville, differing chiefly in having a smaller proportion of salts of lime. They are stated to be found very useful in diseases of the urinary organs, gout, diseases of the liver, and constipation. The book, however, is not confined to a description of the spa, and of the cases in which it is likely to prove useful, but gives a good account of the Vosges and its people, with a considerable amount of information respecting the antiquities of the place, the customs and usages of former times, the manners and character of the people, their superstitions and prejudices. There is also a description of the principal places of interest within reach of Vittel, and the best means of visiting them. It will be found a useful guide to anyone visiting the picturesque scenery of that part of France. There are two good maps of the country round Vittel and Gérardmer. The chief defect in the book is the want of an index.

Schinznach in Switzerland; its Situation and Therapeutic Advantages. By Dr. DE ZYMOWSKI, Resident Physician. With a Preface by Dr. ARTHUR HASSALL.—The baths of Schinznach, once known as the baths of Hapsburg, are of ancient date. The spring which supplies them was discovered as far back as 1692. It is said to contain the largest amount of sulphuretted hydrogen of any waters, on the presence of which its curative properties mainly depend. The water as it issues from the spring has a temperature of 91·4° F. It is used principally in the forms of baths and inhalations, and to a less extent for drinking. The baths have recently undergone great enlargement and many improvements. The establishment, consisting of a series of pavilions, is very commodious and complete. Schinznach is situated between Basle and Zurich, on the river Aar, and in the midst of very pretty scenery. The *brochure* of Dr. de Zymowski is very carefully prepared, and is founded on a lengthened experience. In it every necessary detail in reference to the establishment itself and the maladies for which the water is successfully employed will be found.

The Journal of Physiology. Edited by MICHAEL FOSTER. Vol. 8, No. 2.—This part contains:—1. MacMunn: Further Observations on Myohæmatin and the Histohæmatins, with a plate. 2. W. Hale White: On the Histology and Function of the Mammalian Superior Cervical Ganglion, with a plate. 3. J. Rose Bradford: On the Physiological Action of Ulexin. 4. J. Bradford: On the Electrical Phenomena accompanying the Excitation of the so-called Secretory and Trophic Nerve Fibres in the Salivary Glands of the Dog and Cat. 5. W. B. Ransom: On the Influence of Glycerine on the Liver. Lastly, the Proceedings of the Physiological Society, Nos. 2, 3, and 4.

Ambulance Sermons: being a Series of Popular Essays on Medical and Allied Subjects. By J. A. AUSTIN, M.D. Pp. 384. London: Redway. 1887.—To call these ambulance sermons is a misnomer. They consist of a series of papers intended for the instruction of the general public, which appeared weekly in the columns of the *Norwood Review*. They might be described as popular papers on anatomy, physiology, pathology, the practice of medicine and surgery, and several other topics. They are written in a style which, we presume, takes well with the class for whom they are intended. We can but regret the publication of works of this description.

The Scottish Sportsman and Tourist. By ROBERT HALL, pp. 559. London: Simpkin, Marshall, and Co. 1887.—This work cannot fail to prove useful to tourists who desire to spend their holiday amidst the beautiful scenery of Scotland, and especially to those of them who are lovers of the gentle art. It gives a brief description of the different counties, arranged alphabetically, with the towns and villages in each, the lochs and rivers, and the shootings. After reading the description of several of the places with which we are well acquainted, we are of opinion that the work has been carefully compiled and the information it contains is to be relied on. There is an excellent map, which of itself is fully worth the price of the whole volume.

Analytical Records.

AERATED COCAINE WATER—A NON-ALCOHOLIC STIMULANT.

(SHILLINGFORD & Co., BICESTER BREWERY.)

THERE can be no doubt of the genuineness of this preparation, as the alkaloid can readily be separated by the ordinary method and its properties observed. A distinct paralysing action on the tongue was observed in the evaporated ethereal extract in addition to the bitter taste. Of course, the selection of the cocaine is the only difficulty in the manufacture, and this has evidently been effected with due care.

NATURAL KARLSBAD SPRUDEL SALT.

(PREPARED AND EVAPORATED FROM THE KARLSBAD WATER BY THE KARLSBAD MINERAL WATER COMPANY.)

Our analyses agree with those of the well-known Karlsbad water, except that we did not find lithium. We have, however, no reason to doubt that this is the genuine crystallised salt of the spring. The agents are Messrs. Ingram and Royle, 52, Farringdon-street, E.C.

SELLERS' AERATED SALINE APERIENT WATER.

(JOHN SELLERS, FARRINGDON-ROAD, LONDON.)

An artificial mineral water in which the characteristics of some of the well-known continental springs have been imitated successfully. Artificial mineral waters have at least one advantage over the natural ones, since it is easy to keep their composition absolutely constant, whereas some variation is apt to occur in the natural ones. The present preparation may certainly be described as a useful and safe aperient.

RUBINAT-CONDAL MINERAL WATER.

(J. W. VICKERS, NICHOLAS-LANE, LONDON.)

This very powerful aperient water is said to come from the Condal spring at Rubinat, Lérida, Spain. Its chief constituent is sulphate of sodium, but other sulphates and some chlorides are present, as well as a distinct trace of iron. The total solids were found by us to amount to 4175·5 grains per gallon, and a sample analysed by the Professor of Chemistry in the University of Barcelona contained no less than 7050·764 grains, a most unusually large quantity.

ANTI-RHEUMATIC MUSTARD OIL.

(MOSS, RIMMINGTON, & Co., SELBY.)

There can be no doubt that this preparation is what it is described to be, pure mustard oil, the true sulpho-cyanate of allyl. Gently heated, or distilled with water, the light ethereal oil known as crotonitril, which is always present in natural mustard oil, passes over, while the oil itself boils at 150°C. (312°F.) It can be applied easily by rubbing, and is a convenient and useful remedy.

BROMO-SODA.

(PREPARED BY W. R. WARNER & Co. AGENTS: F. NEWBERY & SONS, LONDON.)

This is an effervescing preparation of bromide of sodium and caffeine. Each is easily found by analysis, and the only novelty seems to be the use of the sodium instead of the potassium salt. The sodium compound does, in fact, agree better with some stomachs, and in some nervous affections the bromo-soda will be valuable.

COMPOUND SYRUP OF HYPOPHOSPHITES.

(LORIMER AND Co., HANGRAVE-PARK-ROAD, LONDON.)

This is a well-prepared mixture of various hypophosphites with minute quantities of quinine and strychnine. The constituents and the quantities of each present are very properly described upon the label, so that the physician will have no doubt as to what he is using. Our own analysis confirms the statement of the manufacturers in regard to every one of the constituents.

OVER-PRESSURE IN AUSTRIAN SCHOOLS.

THE Austrian Minister of Public Instruction has just issued a report, compiled at his special instance, on the "Ueberbürdung der Mittelschüler," or the over-pressure prevailing in intermediate schools. Dr. Joseph Heim leads off with a distinct admission that, except for pupils who are unusually favoured in mind and body, the Austrian system of middle-class education is chargeable with over-pressure and all its attendant evils. This state of things had long been suspected, and two years ago the Minister of Public Instruction subjected these schools to some wholesome reforms from the purely hygienic point of view, with the result of putting into more prominent relief the harm they do by mental overstrain. The working capacity of the young, it is found, has been greatly exaggerated, and to relieve the *courbature cérébrale* thereby induced, it proposed, among other innovations, to make a better division of the school holidays by giving never less than from twelve to fourteen days' respite from work at Christmas and at Easter. The curriculum of study is not blameworthy, but the method of study (according to the report) is particularly so; and practical reforms are suggested in diminishing or doing away with the abuse of written exercises and that of committing too much to memory. Dr. Heim concludes by suggesting the formation of a committee, to consist of schoolmasters and medical men, with a view to reforming the traditional modes of instruction and to consulting the physical not less than the mental growth of the young. His general report is then followed by four special ones, on which his conclusions are chiefly based. The first of these is by Dr. Adolf Löffler, who finds that the reformer must take special cognisance of the matter of instruction, and, for one thing, reduce its quantity; that a maximum of the hours of school attendance must be fixed; that home tasks must be regulated; and that a less exacting system of examinations must be devised. The second is by Dr. Hans Adler, who deals with the best mode of sparing the eyesight of the scholar. The third is by Dr. Leopold von Schrötter, who discusses the questions of physical development and ailments peculiar to the young; and the fourth and last is by Professor Theodor Meynert, who considers over-pressure in its effects on the nervous system and on the mind. This Austrian official document, in which schoolmaster and physician have worked harmoniously to ascertain the truth, and in which they give their conclusions with caution and calmness, should be welcomed by those among ourselves who are anxious that an all-important, while much agitated, subject should be approached in the spirit of science, correcting abuses where they exist, while withstanding all innovation conceived in panic and brought forth in imprudence.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE annual meeting of the Medico-Psychological Association was held at 11, Chandos-street, Cavendish-square, on Wednesday, July 27th, 1887, under the presidency of Dr. F. Needham. There was a numerous attendance of members. A vote of thanks was accorded to Dr. Savage, the retiring President. Dr. Clouston was elected President for the year 1887-8, and it was decided that the next annual meeting should be held in Edinburgh. The Association's certificate of competency in psychological medicine was stated to be now held by twenty-four gentlemen, who had satisfactorily passed the necessary examination, and the Association Prize and Medal were reported to have been awarded to Dr. Wigles-worth for his essay on Pachymeningitis. The Gaskell Prize (£30) has been awarded to Dr. Mortimer, of the Portsmouth Asylum. At the afternoon meeting Dr. Needham read his presidential address, which was followed by a long discussion on the subject of the new Lunacy Bill, in which discussion part was taken by Drs. Maudsley, Wood, Clouston, Rayner, Manning (of New South Wales), Urquhart, and Hack Tuke, and Mr. Clarke Bell, president of the Medico-Legal Society at New York. The members and visitors subsequently dined together at Greenwich. The following gentlemen passed the examination:—E. M. Thompson, M.D., Bellaghy, Castle Dawson, county Derry; W. Arnison Slater, M.R.C.S., Fisherton House, Salisbury; Edgar English, M.R.C.S., Manor-road, Stoke Newington; Samuel Simpson, M.B., D.Ch., Bethlem Hospital; Robert Nairn, M.R.C.S., L.R.C.P., Bethlem Hospital; J. Desmond E. Mortimer, M.R.C.S., Portsmouth Borough Asylum.

THE LANCET.

LONDON: SATURDAY, AUGUST 6, 1887.

THE draft of the Charter which has been adopted by the Councils of University and King's Colleges for presentation to the Privy Council, which we have printed on another page, marks an important stage in the history of educational work in London. It will hardly be believed by many that these two rival institutions, considering their origin and past history, could have been brought into accord and joint action, even for their common benefit; but the march of time has softened down the bitter feelings and mitigated the asperities which were left as a legacy by their founders, and the two Colleges have, by the necessities of a large reform in the educational methods at present existing in the metropolis, and the hopeful prospect of a formation of a Teaching University in London, been driven into a combined action and a close communion. The wise aims of the founders of the University of London, which were so ruthlessly disregarded when the professors and teachers were deprived of all connexion with the University in 1858, and when certificates of studentship were dispensed with in all the Faculties except Medicine, are now likely to be carried out, but by another and a new body. The University of London since then has confined itself to examining, and has well and ably discharged this function. The number of candidates who have passed through its portals has enormously increased, and is still increasing; but in restricting its usefulness, so far as collegiate students are concerned, it has completely changed its character and objects, and has deliberately chosen to follow a path which was never dreamt of, much less intended, by its founders and its early friends. Instead of exercising a due and proper influence on the "higher teaching agencies in the metropolis, and making London a great seat of learning," it is now only an examination centre for the empire, and has no local utility and is of no local benefit. The more closely its work has been adapted to an imperial end, the greater has been its departure from its original purpose. Hence the necessity for a real Teaching University in London is now as great, or even greater than, when the University of London obtained its Charter in the year whose jubilee it is now celebrating. It could scarcely have been expected that the largest and most important colleges affiliated to the University would bear the new departure of 1858 with equanimity. The secession of Owens College in 1880, and the great strides made by that college since its incorporation with the University College of Liverpool into the Victoria University, have necessarily given a powerful impetus to the movement in favour of establishing a similar institution in London. The admitted need for giving London students proper facilities for obtaining medical degrees, and the impossibility of so modifying the University of London as to meet this want, have also encouraged the supporters of this movement. A University conferring degrees in Medicine only is almost without a precedent, and will be opposed by nearly every University graduate of standing and influence in the kingdom, as well as by the other medical corporations; whilst a real Teaching University in London, with power to confer degrees in Arts, Science, and Medicine, must have the sympathy of all who are interested in the educational welfare of the metropolis—excepting, of course, those who are officially or closely connected with the existing University, and who cannot be expected to favour the foundation of an institution designed to carry out the work for which their own Charter was originally granted. The secession of Owens College was a successful protest against their system, and has obviously influenced the present application for a Charter by the two largest London Colleges—indeed, the only fully equipped Colleges in London,—so that London, like other cities, may have a local University for its students. The reasons for the creation of a Teaching University for London and the adjacent district, with its four millions of inhabitants, seem to us so urgent that we would fain hope that the present University, so much wider in scope and aim, will not, by a narrow and selfish opposition, repeat the mistake of the older universities when its own formation was under consideration. The objection to placing the examinations and the conferment of degrees in the hands of the teachers is of little real importance, and could only be advanced by the most thorough-going worshippers of the examination-by-result system. We could hardly have believed that this old conceit of Lord SHERBROOKE, which would seem to have been buried in the controversy about Owens College eight years ago, would again be seriously brought forward. Teachers, when assisted by external examiners as assessors with equal authority, make the best examining board; and if there were any valid objection to the plan so generally followed, it would have been discredited and discarded long since. But with the so-called exception of London, such a system is at present adopted by all the English and Scotch Universities, old and new alike. Even in the case of London most of the examiners are teachers, and many of them must of necessity examine their own pupils; so that if this ground of objection is to be adopted by the Senate, it will first have to look at home, for the Senate can only appoint examiners, generally teachers, and cannot influence their decisions or results.

The new Charter is drawn on a wide basis, and gives no pre-eminence to the medical departments of King's or University Colleges, but provides for the admission of all the medical schools in the metropolis, so as to form a Medical Faculty. Looking on the two Royal Colleges as the representatives of the London schools, it allots to them the same number of representatives on the Senate, and therefore an equal power, as is given to University and King's Colleges. It is yet to be hoped that the Royal Colleges may join in this important educational movement; but if they still decline, we suppose that the constitution of the Senate will be modified so as to secure a direct representation of the schools, instead of the more convenient one at present suggested. The only paragraph in the Charter to which exception can fairly be taken is in Clause 5—"Provided that no ordinary medical degree shall be conferred on any person who shall not previously have obtained a qualification for registration under the Medical Acts." This,

Digitized by Google

doubtless, is inserted in deference to the oft-repeated desire that no new qualification for practice should be added to those which are already in existence, and which are universally allowed to be far too numerous. It will turn aside a large amount of opposition, but must necessarily increase the cost of the new degree.

THE Dublin meeting of the British Medical Association will be memorable for the remarkable Address in Medicine delivered by Professor GAIRDNER. No one can have listened to his words, and no one can now peruse them, without being struck with the command of his subject that the orator exhibited, and with the weighty, almost judicial, character of his utterances. His theme was the old one, "Are we better than our fathers?" and was suggested by the famous passage in which Sir WILLIAM HAMILTON asks whether the practice of medicine has made any advance since the days of HIPPOCRATES. The learned philosopher may have put this question with a half cynical intent, or, on the other hand, he may have been so shaken by the diversity of medical doctrines and practice as to intend it in all seriousness. It was taken up and answered, as Professor GAIRDNER says, by Dr. WARBURTON BEGBIE before the Association twelve years ago, yet no one will deem the question unworthy of a fresh examination, especially when this is made by one so competent and so well versed in medical doctrine as Professor GAIRDNER. He has, as he truly says, been a teacher of medicine all his life, and is therefore in a position to speak with authority upon the great revolution which has taken place in the methods of medical practice.

No one, of course, will take it in its literal sense that the practice of HIPPOCRATES, or rather of his interpreter GALEN, has continued unshaken to the present day. Undoubtedly there are some points of detail which have not varied, for which even modern physicians are indebted to the sagacity and foresight of the ancients. But have we departed from the tradition of their work? Are we really so much in advance as we boast ourselves? In other words, Has medicine yet emerged from empiricism? Has it ceased to pin its faith to vague theories? Is it, as Professor GAIRDNER puts it, really more *stable* than it was a century ago? This, after all, is the real test of advance in the healing art; and, tried by these questions, there are, it must be confessed, many signs of absolute want of progress. In truth, there is no physician who will not confess that, in spite of the very notable achievements in the building up of the science of medicine, and in basing our practice upon the firm foundation of observed facts, there are yet wide regions in which we are still groping in the darkness, where we rely upon the "art" that clings to us from the past. It is slow and weary work, this casting off of old traditions and searching for the sure ground of fact; but it is being done, and that with increasing energy and hope. Professor GAIRDNER, in his calm and impartial survey, showed us what comfort we may glean from such reflections, and we may confidently look forward to a time when rational medicine will prevail; though, in spite of the many disheartening indications we could point out of the spread of quackery among the public. For [illegible] not only the medical man who has to be imbued with [illegible] spirit, his patients also sadly need enlightening upon the subject. The old faith in medicine as a mysterious and wellnigh miraculous power has not yet died out, and it is fostered by the unscrupulous, who trade on ignorance and folly. But how is it with ourselves—we the legitimate heirs of Hippocratic medicine? Are we really worthy of the laudation we are so apt to indulge in, and have we wholly thrown off the shackles of tradition? It seems to us that Professor GAIRDNER supplied an answer to this question, and, indeed, the only possible answer. He showed that, strictly speaking, we have no data of comparison between the medical practice of our day and that of HIPPOCRATES or GALEN. We have their dicta and their principles, but we have no clinical records sufficiently detailed to contrast the efficacy of their methods with that of our own. No one can deny the great service rendered by "the Æsculapian priest who first emancipated the art of medicine from the trammels of priestly control on the one hand, and of philosophic dogmatism on the other," and, wide as is the interval between his days and ours, there is still much in the Hippocratic tradition that remains unshaken. In order, however, to point the contrast between the old and new medicine more strikingly, Professor GAIRDNER selected the name of CULLEN, who a century ago faithfully maintained the principles of that tradition. CULLEN'S teaching was sound and well-reasoned, and yet it was shaken to the roots by the fanciful and extravagant doctrines of BROWN. For a time the Brunonian system dominated the medical world, which was never more unstable in doctrine than at the close of last century.

"It seemed," said Professor GAIRDNER, "as if the medical mind, oscillating between the claims of humoralism and solidism, and vitalism, could find no resting-place, but was constantly exposed to be drawn out of the path of traditional medicine by any new theory which presented a certain amount of apparent simplicity and plausibility—all the more if it contemptuously dismissed, as unworthy of serious study, the laborious and positive acquisitions of clinical and pathological fact, which had even then been largely gathered in, especially by Morgagni, as to the natural history of disease; and this was exactly what the Brunonian system did."

Well, the Brunonian system enjoyed its brief day of triumph, and has now fallen into merited oblivion. The progress of science has, we may trust, put an end once and for all to extravagances of that sort, although, to be sure on a minor scale we even now occasionally meet with generalisations which go far beyond the limits imposed by the facts on which they are based.

Contrasting the times of CULLEN and BROWN with the present, Professor GAIRDNER sought for evidence of a greater stability in medical doctrine now than then. He surveyed the field of modern medicine, and showed that in some respects, especially in the overwhelming rush after new remedies, we have not much to boast of. There is no gainsaying that in some directions medicine has attained as great a stability as it is possible to conceive, but the problems are so vast and numerous that we cannot marvel at the uncertainty in which we often still remain. Happily, however, we are no longer dominated by any theoretical system of universal application, and we are daily striving to rid ourselves of all that is empirical in practice. We have this advantage over CULLEN, that

Digitized by Google

we are learning more of the nature of disease and of the action of remedies than was known to him, and our practice is becoming simpler and sounder in proportion as that knowledge widens. Amongst the hopeful signs of an increasing stability in medicine, Professor GAIRDNER adduced the advance of sanitation, the recognition of the self-healing powers in acute disease, the banishment of venesection (or rather its rational restriction) as a remedial measure, and the more enlightened practice of feeding the fever patient rather than bleeding or over-stimulating him. These are, indeed, great signs of progress, and separate us from the practice in vogue long after CULLEN'S day by an immeasurable distance. Up to that time it might have been questioned whether Sir W. HAMILTON'S query was not justified, but no one dare assert it now. The Hippocratic tradition has been broken in its strongest link. Professor GAIRDNER himself has been the witness of this revolution, and has taken no small part in furthering it. There is no doubt that in these respects at least we have gained wisdom, and it has come to us not through the adoption of any theory or as a revulsion from "orthodox" practice, but as the outcome of that patient investigation of natural phenomena of the healthy and diseased body and its environment which forms the basis of scientific medicine. That the gain is a substantial one is to be seen in the instance cited by Professor GAIRDNER of the treatment of fevers; for although the precise value of antipyretic methods is not fully proved, there can be no question of the gain derived from the change from lowering to restorative methods, and the substitution of easily assimilated food for excessive doses of alcohol. There still remain many branches of medicine in which art lags behind science, and there are prejudices and traditions, both among the laity and the profession, to be eradicated before we can be satisfied with real progress. Therefore it was well to be reminded of our position, and no occasion could have been more appropriate than that of which Professor GAIRDNER has availed himself, when medical practitioners from all parts were gathered together to hear of "new things," and to exchange experiences. His address will have served the useful purpose of impressing his hearers with a befitting sense of humility, and encouraging them to further effort in the cause of rational medicine.

IN the long interval of the sessions of the General Medical Council the profession looks with some interest to the action of the Executive Committee, which is invested with the powers of the Council with regard to certain questions, and which was enlarged at the last meeting of the Council. The Executive Committee met on the 25th of June, and we may well suppose was fully occupied in dealing with several questions which had been referred to it. Our readers may remember that at the meeting of the General Medical Council in November last, its attention was drawn to the subject of Unqualified Assistants, or rather to its own resolution (April 21st, 1883) on the subject—especially referring to charges of gross misconduct in the employment of unqualified assistants and charges of dishonest collusion with unqualified practitioners in respect of the signing of medical certificates required for the purposes of any law or lawful contract, and to the fact that such charges are, if brought before the Council, regarded by the Council as charges of "infamous conduct" under the Medical Act. The Council in November resolved to make public these views on this subject. Until the meeting of the Executive Committee last week no steps seem to have been taken to give publicity to the Council's serious estimate of such conduct and such collusion between qualified practitioners and unqualified persons. As will have been seen by our last issue, copies of the resolution passed have been formally published in the Journals of the profession, so that henceforth there will be no excuse for not knowing how such conduct will be punished by the Medical Council. It is only fair that support should be given to the Council when it thus does its duty and tries to protect the public from all unreasonable and illegal uses of unqualified persons. Another duty delegated by the Council to its Executive Committee in May last was that of carrying out the Council's resolutions in regard to the Inspection of Examinations. It is understood that part of the business of the Executive Committee at its meeting last week was to prepare a letter of instructions to the inspectors under the new Act, on whom the arduous duty is devolved of inspecting the examinations in Medicine, Surgery, and Midwifery of all the examining bodies in England, Scotland, and Ireland within a period of twelve months. Strictly speaking, the Act requires the inspectors to ascertain the sufficiency of the examinations as a test of competency to practise. They are not required to interfere in the examinations, but to report on their sufficiency or insufficiency, and any other matters in relation to such examinations on which the General Council may require them to report. At the meeting in May the Council resolved that it should be an instruction to the inspectors to give special attention to the quality of the Practical Examinations and to the sufficiency of the means and appliances which are in use in them for testing the qualifications of candidates. We may be sure that the instructions of the Executive Committee covered this and all other important points. Amongst other matters relegated by the Council to its Executive Committee was the reception and consideration of applications for the Registration of Foreign and Colonial Degrees under the Medical Act, 1886. This is a matter of great importance. On the one hand, many gentlemen holding foreign degrees are very anxious to see them recognised and registered. On the other hand, it is the clear duty of the Council not to proceed to register foreign and colonial degrees in any haphazard way, but after due inquiry and consideration. Even in the case of gentlemen already on the Register in virtue of British qualifications, but holding foreign degrees till now unregistrable, the Council is bound to satisfy itself as to the nature of the examinations to be passed in order to obtain such degrees. To do this is a process which requires time. It is not sufficient to learn even the proportion of rejections to passes in such examinations. This might be large, and yet the examinations might not, in the judgment of the Council, be "proper" examinations. Nevertheless, it is clearly not the design of the Act that the Council should be fastidious or hypercritical, and if it showed any disposition to be so it is liable to be overruled by the Privy Council. The Privy Council will not

Digitized by Google

however, be likely to show any disrespect to the judgment of the Council formed on sound data. The great majority of applications for the registration of foreign and colonial degrees are from practitioners already on the Register, and most of these hold the degree of Brussels. There are 222 applications in all, and of these 177 are under Clause 16, from practitioners already registered. The work of inquiry is proceeding, and the Executive Committee has appointed a sub-committee to prepare a report as to the evidence of satisfactoriness in foreign degrees. We gather that various other matters occupied the attention of the Executive Committee, some of which were serious, and will probably have to stand over for the judgment of the General Medical Council.

THE greater part of the water supply of London is, it is well known, drawn from the Thames above Hampton. Twenty years ago it was a matter of keen controversy whether such a supply was suitable for the metropolis, and a Royal Commission was appointed to inquire into the matter. The report of the Commissioners was signed on June 9th, 1869, and their conclusions were so definite and so strongly worded that from that time to the present they have been pretty generally accepted as final. It is not surprising. The Commissioners in their summary pointed out difficulties of a grave kind in regard to each of the alternative schemes laid before them, and expressed their deliberate opinion that the present supply was sufficient in quantity and quality. As to the quality, they said: "We are of opinion that there is no evidence to lead us to believe that the water now supplied by the companies is not generally good and wholesome." The opinion was, however, supplemented by several admissions which tended to diminish its value. Thus we read that "perfect filtration is highly essential to the good quality of the water supplied"; "that this process is at present in many cases very imperfectly performed"; and further on (to take the most important qualification of all), that "when efficient measures are adopted for excluding the sewage and other pollutions from the Thames and the Lea and their tributaries, and for ensuring perfect filtration, water taken from the present sources will be perfectly wholesome and of suitable quality for the supply of the metropolis." We have said that these conclusions stopped for a time all further discussion, for the dicta of a Royal Commission of experts are not to be lightly set aside. And yet from the beginning there was no consensus of opinion in their favour. For one thing, the Commission was imperfectly constituted. The members were worthy of respect, and two or three were eminent, but no one was a physician or a chemist, and as water supply is above all a question of public health, this defect was serious. Then, again, the conclusions themselves were contradictory; for whereas in one passage the present supply was described as "generally good and wholesome"—which surely implies a satisfactory state of things,—in another a condition which is practically impossible was [illegible], that efficient measures should be adopted for excluding sewage and other pollutions from the river. Some [illegible] was undoubtedly done by the Commission, for the London companies were stimulated to increased exertion in regard to filtration and constant supply, and Londoners now reap the benefit of the agitation. But scientific sanitarians have never been satisfied, for the certainties, to say nothing of the risks, of pollution in such a water supply are too obvious to escape attention from those who know anything of the laws of zymotic disease. For ourselves, we may fairly claim that we have never hesitated in our view of the case, and have always stated our belief that the present water supply of London is fraught with incessant danger, and that, however smoothly things may go at present, there is a permanent possibility that at any time a serious calamity may occur. That dread sanitary teacher, the cholera, whose lessons are always respected, and to whom England probably owes ten times more lives than deaths, has once more cast his shadow, though not as yet his substance, over us, and once more there is some sign of public interest in the purity of the water we drink. The terrible example of Spain is not yet forgotten, and we have therefore some hope in asking once more the question, Is our water supply safe? Serious assertions in respect to it have reached us, and we have thought it our duty in the public interest to institute new inquiries, the results of which we shall duly lay before our readers.

THE Court of Appeal has decided against the Medical Council in the appeal by the Council against the judgment of the Divisional Court (Mr. Justice MATHEW and Mr. Justice A. L. SMITH) in favour of Mr. PARTRIDGE'S application for a *mandamus* to the General Council of Medical Education of the United Kingdom to restore his name to the Register of Dentists kept under the Dentists Act of 1878. The facts will be remembered by our readers. They are stated thus in *The Times* report:—

"The applicant had practised as a dentist in the metropolis since 1867, but he never registered in respect of this qualification. In 1878 an Act was passed requiring dentists to be registered under that Act, the General Council of Medical Education of the United Kingdom being made the governing body. In 1878 Mr. Partridge obtained from the Royal College of Surgeons in Ireland a diploma in dentistry, and as a licentiate of this body, which was one of the medical authorities referred to in the Act, he applied for and procured registration under Section 6 of the Act. The diploma had been granted on the terms that the holder should not seek to attract business by advertising or by any practice considered by the College unbecoming, and that the diploma might be cancelled on its being proved to the satisfaction of the President and Council that he had done so. In 1885 the Royal College of Surgeons in Ireland cancelled the diploma on the ground that Mr. Partridge had advertised for business, and upon this being brought to the notice of the General Council, they directed his name to be erased from the Register. It was argued for Mr. Partridge that the General Council had only power to erase his name for some cause specified in section 13, which provides that where a registered person has been convicted of an offence, which if committed in England would be a felony or misdemeanour, or been guilty of any infamous or disgraceful conduct in a professional respect, that person shall be liable to have his name erased from the Register. It was argued on behalf of the General Council that Section 11 bound them to keep a Register, and that that must mean a correct Register, and as the diploma, by virtue of which Mr. Partridge got registered, had been taken away, he was not entitled to be on the Register."

This decision is scarcely likely to be further contested.

Digitized by Google

The opinion of Justices MATHEW and SMITH was regarded by lawyers as pretty decisive and very authoritative, though it left the applicant in the absurd position of being entitled to be replaced on the Register after the Body from whom his diploma had been received had withdrawn it, and the Council in the absurd position of being required to keep a man on the Register who had ceased to have a registrable qualification. But mere absurdity does not constitute illegality; and the Medical Council, or its legal advisers, must bow with what grace they may to a decision of the Court of Appeal, which negatives one of their favourite principles of procedure—to remove from the Register, without further inquiry, a man whose diplomas have been withdrawn.

The Council has this consolation, that the judgment of the Court in no way derogates from the Council's high judicial functions. It does not question the right of the Council to remove Mr. PARTRIDGE'S name from the Dentists' Register if it shall see fit to do so. On the contrary, it rather asserts all this in a way to magnify the responsibility of the Council. The Court of Appeal lays down only that the Council erased the name in a wrong sort of way. It did not institute an inquiry into the facts and satisfy itself of the nature of the conduct attributed to Mr. PARTRIDGE. The Council should have acted without reference to the College of Surgeons of Ireland and their reasons for withdrawing their licence. Had it done so, the result might have been altogether different. His lordship said "the *mandamus* must go, but the fact of its going would not take away the power of the General Medical Council to exercise their jurisdiction under Sections 13 and 16, and if on inquiry the Council came to the conclusion that the applicant had, by breaking the conditions imposed upon him by the local medical body, been guilty of disgraceful professional conduct (and if he wilfully broke the condition, his professional conduct might be thought disgraceful), they would erase his name from the Register." Such a judgment will throw much more responsibility on the Medical Council and much less on the medical authorities. Each of these in turn has been too apt to shirk such responsibility; but this judgment will at least clear the air and let the Council know its duties.

Annotations.

"Ne quid nimis."

THE ARMY MEDICAL DEPARTMENT.

WE observe with much satisfaction that Sir Thomas Crawford, at the meeting of the British Medical Association, entered his protest against the course which the Parliamentary Bills Committee had taken on the question of relative rank. He gave an unqualified contradiction to Mr. Hart's statement that the officers of the department were afraid to make any representations on the subject, as it would "not hasten" their selection for promotion. Sir Thomas was supported in his opposition to the report by Dr. Ince, late of the Indian Service, Deputy Surgeon-General Joynt, and Mr. Macnamara, who is an old army medical officer. Sir Thomas Crawford moved that the paragraph on relative rank be omitted from the report, and referred back to the Council for reconsideration. After some discussion this course was adopted, Mr. Hart stating that he did not object to it provided it was "not regarded as a vote of censure on the committee." Sir Thomas Crawford disclaimed all idea of censuring the committee, but it is difficult to regard the resolution in any other light. We are glad, for the credit and honour of the department and of the profession, that the Director-General has taken this course, and that he has been so well supported in it by the members of the Association. The *plébiscite* of the army medical officers we consider an unwise and unwarrantable act, one which, apart from its bearing upon the discipline of the department, cannot but be interpreted as an undeserved reflection on its distinguished head.

A CLINICAL EXAMINATION!

WHAT constitutes an examination in clinical medicine? The ordinary mind conceives it to be the examination of a candidate by the bedside of a patient, with all the appliances and reagents at hand for making a thorough investigation and record of the case. That, too, is the sense in which it is interpreted by the universities, and so has it been interpreted until this year of grace by the body which one might expect to set a worthy example in the matter—viz., the Royal College of Physicians. But, whether from the association with the College of Surgeons and the force of example or not, it has strangely deviated from this principle since the two bodies took possession of the Hall on the Embankment. Thither are now summoned the halt and lame, and candidates for the licence of the College are "taken over" these cases, of whom, we are assured, there is a plentiful supply, who are not too ill to attend. This is a poor substitute for the hospital ward, and in adopting it the College has wittingly placed itself on a level with the Society to which it professes to be so superior. What can be the reason? Is it to save trouble? Perhaps it is, and that may be the reason why the examiners concur in it. But such a ground should not weigh for an instant, either with those who regard the matter from the point of view of the candidate, or from that of the public who demand a thorough qualification, or even from that of the dignity of the College. Have we not been told that London is the greatest storehouse of clinical material in the world? Do we not know that the number of beds in its hospitals and infirmaries can be reckoned by the thousand? And yet the College of Physicians must descend to this paltry substitute for a thorough clinical examination. No matter how numerous the candidates, there need be no difficulty in assigning them cases in hospital wards; whilst there would be no great difficulty in appointing assistant examiners to conduct this part of the examination if the burden were found to be too heavy for the staff of examiners. We do not hesitate to say that the examination, as at present conducted, does not, and cannot, attain the level it ought to reach; and that so long as this style of conducting it is pursued no one can say that in clinical medicine the College of Physicians applies as good a test as the Universities.

ACUTE HEPATIC CIRRHOSIS.

THE varieties of hepatic cirrhosis are very numerous, and the tendency is rather to increase their number, whilst the desire must surely exist to put this seeming chaos into order. Much light has yet to be thrown on the acute forms of cirrhosis, with which we seem to be becoming more and more familiar. M. Debove has contributed an account of an interesting case to the "Bulletins et Mémoires de la Société Médicale des Hôpitaux de Paris," No. 13. The whole duration of the clinical history was not more than five months, and for the first three of these the woman, aged thirty-four, merely complained of some general symptoms not specially referable to the liver, the first symptom

Digitized by Google

affection of which organ was marked jaundice, and on admission to the hospital it was found that the liver extended five fingers' breadth below the margin of the thorax. Fever, jaundice, hæmorrhages, enlargement of the spleen, diarrhœa, and but slight ascites, were the principal symptoms. Three weeks before death the liver progressively diminished in size, till at the necropsy it was found to be level with the edge of the ribs. The cirrhosis had chiefly affected the periphery of each hepatic lobule, and was in this sense allied to the monolobular form of Charcot, for the amount of connective tissue increase was about sufficient to replace that of true liver tissue, so that the volume of the organ was not far from normal. Further examination showed, however, that a peri-cellular sclerosis had also taken place, and that the connective tissues around the portal system as well as around the hepatic veins were increased; the surface and section of the organ were granular. The remaining true liver cells were either fattily degenerated, recalling the fatty cirrhotic type, or else granular and atrophied. Debove believes that neither alcohol nor syphilis was operative in the causation of the disease, which he was unable to explain.

THE METROPOLITAN ASYLUMS BOARD.

THE Metropolitan Asylums Board again on Saturday received reports of the freedom of their institutions from cases of small-pox, but one patient suffering from this disease having been admitted during the fortnight preceding the day of meeting. Scarlet fever, however, is more prevalent, the numbers under treatment having increased during this period to 594, altogether 634 cases of fever remaining in the hospital. The need for the provision of further accommodation had to be considered, and it was decided that the Ambulance Committee should be asked to advise as to the reopening of the North-Western Asylum at Hampstead. The Board also received, through the Local Government Board, a communication from the Surrey magistrates respecting the accommodation of harmless lunatics; the county asylums were full, and it was thought that room for a larger number of chronic imbeciles could be found in the asylums of the managers. The Board at the present time has 5408 patients of this class under treatment, as well as 552 boys on board the *Exmouth* training ship.

FRUIT AS A FOOD.

No great time has elapsed since we had occasion to make a few remarks on the value of fruit as a form of light diet, and to refer to a few simple rules which those who partake of it do well to observe. Taken in the morning, fruit is as helpful to digestion as it is refreshing. The newly awakened function finds in it an object of such light labour as will exercise without seriously taxing its energies, and the tissues of the stomach acquire at little cost a gain of nourishment which will sustain those energies in later and more serious operations. It is an excellent plan, with this object in view, to add a little bread to the fruit eaten. While admitting its peculiarities of these valuable qualities, however, and while also agreeing with those who maintain that in summer, when the body is, at all events in many cases, less actively employed than usual, meat may be less, and fruit or vegetables more largely used as a food, we are not prepared to allow that for [illegible] an exclusively vegetarian regimen is that naturally advisable. Meat provides us with a means of [illegible] albuminoid material, which is indispensable in the [illegible] assimilable form. It affords us in this [illegible] only an important constituent of tissue growth, but [illegible] of the whole process of nutrition. It has [illegible] real, definite, and great value in the ordinary diet of man, and the wholesomeness of fruit combined with farinaceous food as an alternative dietary is not so much an argument in favour of the vegetarian principle, as a proof that seasonable changes in food supply are helpful to the digestive processes and to nutritive changes in the tissues generally.

HEALTH CONDITION OF HOLIDAY RESORTS.

THE Registrar-General, in his Quarterly Return, just issued, publishes his usual table of the recent mortality statistics for the registration districts and sub-districts containing forty-six of the principal seaside and inland holiday resorts. This table gives the death-rate from all causes, and from the principal zymotic diseases in each of these watering places of England and Wales. It appears that they had an aggregate population estimated at rather more than a million persons in the middle of this year. Among this population the mean annual death-rate during the three months ending June last did not exceed 15·5 per 1000, which was 1·7 below the mean rate in the aggregate of the rural districts of England and Wales. The death-rate from the principal zymotic diseases in those watering places was as low as 1·03 per 1000, against 1·50 in the whole country, excluding the seventy-eight largest towns. It is therefore evident that, taken in the aggregate, the health condition of these holiday resorts during last quarter, judged by their mortality statistics, was eminently satisfactory. Bearing in mind the small population of some of these watering places, and the short period of time embraced by the Return, any attempt to estimate the comparative healthiness of the individual health resorts from these figures of the Registrar-General is to be strongly deprecated. As regards the information relating to the mortality from the principal zymotic diseases, it should, however, afford satisfaction to those proposing to visit Herne Bay, Margate, Bognor, Weymouth, Lyme Regis, Tenby, Aberystwith, Beaumaris, Buxton, and Matlock, to know that during the three months ending June last not a single death from any of the principal zymotic diseases was registered in any of these towns; while in but fourteen out of the forty-six watering places did the death-rate rate from these diseases exceed 1 per 1000. Only in three of the older health resorts did the zymotic death-rate exceed the general average for the whole country.

ST. GILES'S-IN-THE-FIELDS.

THE report for the year ending March 25th, 1887, by the Board of Works of St. Giles's gives an interesting account of sanitary progress in this well-worked district. Of the more important improvements, that of the Shelton-street area undoubtedly comes first, and the Board are to be congratulated on the perseverance with which they have endeavoured to induce the Metropolitan Board to put in force the Artisans and Labourers' Dwellings Act of 1875. We have recently given account of the inquiry held by Mr. D. Cubitt Nichols for the Secretary of State for the Home Department, the result of which has been that the Home Secretary has now brought in a Bill to obtain powers for the clearance of this area. The provisions of Torrens' Act have enabled the District Board to improve a large number of houses in Dudley-street and a common lodging-house in Black-horse-yard; and for the better control of houses let in lodgings some valuable regulations have been adopted which have been confirmed by the Local Government Board. Mr. Lovett gives as the death-rate of the whole district 22·9 per 1000: that of St. George's, Bloomsbury, being 16·5, of St. Giles's North 21·7, and of St. Giles's South 31·7 per 1000. Speaking of the high death-rate in the last sub-registration district, Mr. Lovett says that undoubtedly the principal cause of this is the insanitary condition of the

Digitized by Google

Shelton-street area, Drury-lane, where the death-rate for the past year was as high as 53·7 per 1000. In comparison may be considered the rates of mortality in the model dwellings which now stand on the site of other unhealthy buildings which have been removed. Thus in the Great Wild-street block, having a population of 1437, the death-rate was 21·5 per 1000, and the birth-rate 43·8; and of 820 people in the Little Coram-street block the death-rate was 18·2 per 1000, and the birth-rate 53·6 per 1000. St. Giles's undoubtedly sets an example to its neighbours, and shows how much good can be done when the sanitary improvement of a district is seriously undertaken by a competent health officer and an active sanitary authority.

THE INFLUENCE OF METEOROLOGY ON MEASLES.

DR. CAMERON, in his second quarterly report on the health of the borough of Huddersfield for this year, discusses the high mortality from measles and the accompanying lung diseases. He reminds his authority that on a former occasion he pointed out that an epidemic of this disease had coincided with a somewhat high barometric pressure, an increasing temperature, considerable variation of day and night temperature, and a scarcity of rain. The poison of measles was, according to his view, prevented by the heavy atmosphere and the absence of wind from getting freely away from the close courts and yards; these courts also lacked the wholesome washing effect of rain, and the infection was kept active by the warmth of day, and the slight condensation produced by the chill of night, and spread rapidly to those who were susceptible of its influence. These conditions, which were characteristic of a similar mortality in 1832, were repeated, some of them in an aggravated form, in 1887. During the second three months of the year the barometer has averaged 30 in., and in none of the thirteen weeks included in that period has it averaged less than 29·6 in. The daily range of temperature has averaged 18°F., and the total rainfall has been only 3·09 in. Together with such rain as fell during the seventh, ninth, and in the week following the termination of the quarter, there was a marked reduction in the rate of mortality. Latterly, whooping-cough seems to have been similarly influenced, and during the quarter as a whole these two diseases caused together a mortality reaching 3·06 per 1000. The details thus contributed are of the greater interest because precise information as to the relation of infectious and other diseases to meteorological conditions is so scanty.

FASHION v. SCIENCE AND HUMANITY.

From a very remote, we may even say a pre-historic, period, it has been the custom of human beings to provide themselves with garments at the expense of the lower creation. From a time almost if not quite as early, animals have been slain to furnish food for man. In our own day, also, both practices exist in operation side by side. While, however, the necessity for flesh as an article of diet is generally admitted, provided that it be used in moderation and combined with vegetable food, the need for taking the life of animals in order to clothe the body, it must be allowed, has been to a great extent obviated by the progress of textile industry, which gives us as woollen fabrics most of what we require for daily wear without depriving a living creature of one drop of blood. Fancy, taste, luxury, utility—one or all of these,—it is true, still order the destruction of countless fur-bearing and feathered beings of a lower grade than ourselves; and we are not prepared to say that, in obeying the mandate, at all events of the last-named authority, man exceeds the privilege of his lordly position. When, however, we find him, at the bidding of a mere fashion, persecuting the life of some harmless and to him otherwise useless race of animals, and this even to the extent of extermination, we blush for the cruel heart of our so-called civilisation. When, for instance, little birds, whose only fault is their beauty, are sacrificed by thousands in a year, in order that their feathers or their bodies should adorn the "softer sex" of our species in hours of enjoyment, we are bound in creature kindness to those helpless members of the world's great family, to condemn the barbaric fancy which is so heedless in its self-esteem. Artificial substitutes can be found for ornaments of this kind, and the counterfeit is not by any means a despicable imitation. The desire for their more general adoption is not, we are sure, limited to ourselves, nor is the hope that other Governments will copy the recent practice of our own by restricting the indiscriminate slaughter which has already lost to the world not a few interesting and beautiful forms of animal life.

THE LUNACY BILL.

AN announcement was made by the Leader of the House of Commons on Monday evening last, to the effect that, among others, the Lunacy Acts Amendment Bill would be dropped by the Government. It is much to be regretted that the tardy act of justice to medical practitioners which the sixth clause of Lord Halsbury's Bill would have effected should be still longer delayed. That a medical man whom professional duty and the course of events have placed in a position in which he must form an opinion as to a patient's sanity, and certify it, should be liable, and that for an indefinite period, to a civil action at the suit of the lunatic with all its incidents of heavy law costs and its contingency of sentimental damages, is a serious blot upon English law. The measure of protection which the abortive Bill would have conferred is all that the profession has ever asked, but it is nothing more than the most obvious justice imperiously demands. On this account we much regret the abandonment of the Government Bill, and we think also that it is hardly fair to medical men that a matter of so great importance to them should have been left to share the fate of a measure so comprehensive and so intricate as the derelict Bill. Surely the sixth clause is sufficiently complete in itself, and of sufficient importance to be passed as a separate Act. In that case the Parliamentary process would have been extremely simple, and the measure might well have gone through without trenching unduly upon the precious remainder of an already protracted session.

CATARACT OPERATIONS IN BRUSSELS.

DR. COPPEZ, chief of the ophthalmic department of the Hospital of St. Jean Brussels, has recently published a report of his twelve years' experience in the management of cataract. He has had 218 cases of soft cataract, including the idiopathic, acquired, congenital, and traumatic varieties. Of these, 104 were treated by aspiration. Secondary cataracts to the number of 168 were treated by various well-known methods. Prouff's operation, which has not come into very general use, is strongly recommended by Dr. Coppez when the capsule is not too thick. It consists in making a small incision in the situation of the old wound and destroying the opaque membrane with an ordinary cystotome. The number of hard or semi-hard cataracts operated upon was 1059; of these 692 were extracted with iridectomy, 113 after a preparatory simultaneous iridectomy, and 254 by means of a simple flap operation. Dr. Coppez now decidedly prefers De Wecker's simple small flap operation. Those who prefer von Graefe's operation consider that De Wecker's plan gives rise to prolapse of the iris and causes so much difficulty in getting rid of the cortical portions that secondary

Digitized by Google

cataracts are rendered much more common after this than after von Graefe's operation. Dr. Coppez has found, however, that by injecting eserine into the anterior chamber the hernia of the iris does not occur as frequently as is supposed, he only having met with this complication twenty times out of 254, and when it does occur, if it is left alone and not excised, it does not, he says, give rise to such trouble as the pinching up of the iris in the angles of the wound during the combined operation. As to secondary cataract, he met with it 120 times out of the 692 combined operations, and only ten times out of the 254 simple operations, which figures speak for themselves. Dr. Coppez now reserves the combined operation for cataracts complicated by central corneal opacity, by posterior synechiæ, or by high ocular tension, and for the second eye in double cataracts where the simple flap operation has proved unsuccessful in the first eye. He is opposed to any artificial maturation, preferring to operate in case of necessity on incomplete cataracts by ordinary methods. If any cortical portions remain he removes them a few days subsequently by the aspirator.

UNREGISTERED DEATHS.

THE facts disclosed at a recent inquest held by Dr. Diplock at West Drayton suggest uncomfortable doubts as to the due accuracy of our registered statistics of mortality, if not of our system of registration. It appears that recently the body of an infant aged eleven months was buried in the parish churchyard without any order for burial from the coroner or the usual certificate of registration from the registrar. As a matter of fact, the child was scalded with boiling water during a quarrel and struggle between the parents, and died from "scalds and neglect," as was proved at the inquest which was held after the body was exhumed. The sexton gave evidence at the inquest, and denied that he knew he was acting illegally in burying without a certificate, stating at the same time that he had on other occasions buried persons without such certificate. The present case sufficiently proves the danger to society from such ignorance or evasion of the legal provisions for securing the due registration of deaths; but it is eminently unsatisfactory to hear that Dr. Diplock in January last had his attention officially called to similar illegal acts by London undertakers, and that a communication made by him on the subject to the Home Office resulted in no action being taken in the matter. It is clearly enacted in Section 17 of the Births and Deaths Registration Act of 1874 that "the person who buries or performs any funeral or religious service for the burial of any dead body as to which no order or certificate is delivered to him, shall, within seven days after such burial, give notice thereof in writing to the registrar, and if he fail so to do shall be liable to a penalty not exceeding ten pounds." The law, therefore, imposes a penalty upon every sexton and officiating minister concerned in the burial of any body without the production of the necessary authority for the burial, unless notice of such burial is sent to the registrar of the district in which the death occurred. As the offence is one committed against the Registration Act, we are at a loss to know why Dr. Diplock should have reported the circumstance to the Home Office, which does not now take official cognisance of civil registration. It would appear that upon the Registrar-General rests the responsibility for instituting a prosecution in such cases, and we fear that nothing short of the publicity which would result from prosecutions would effectually put a stop to this careless neglect of legal enactments, the observance of which is so important in the interest of public safety. It cannot be too generally known that, under the present state of the law it is not illegal to bury the body of a person whose death has not been registered, liability to a penalty of ten pounds is incurred if the registrar of the district is not informed within seven days of the burial.

ARMY MEDICAL SCHOOL AT NETLEY.

ON Friday, the 30th ult., at the close of the fifty-fourth session of the Army Medical School, the results of the examinations were declared, and the various prizes instituted in connexion with the school were given to the successful candidates by Sir Henry Acland, K.C.B., F.R.S., in the presence of Sir T. Crawford, the Director-General, Sir Galbraith Logan, retired Director-General, and a number of distinguished officers of the British and Indian Medical Services. Sir Henry, in his address, paid a well-merited tribute to the valuable labours of Sidney Herbert, Edmund Parkes, and Florence Nightingale in connexion with the department, and bore testimony to the important services done in the promotion of sanitary science by the medical officers of the army. He impressed upon the students the necessity, in these days of progress, of increased attention in scientific and literary culture, and appealed to them to be careful to maintain the character of Englishmen and English gentlemen. After the conclusion of the official work the company adjourned to the ante-room of the mess-house, where Sir Galbraith Logan presented to the Director-General, on behalf of the Army Medical Staff, a portrait of Sir Thomas Longmore, to be hung in the ante-room. It is a three-quarter-length portrait, by Mr. George Reed, and was exhibited last year at Burlington House. It was painted for a number of the medical officers of the British and Indian Services, who desired, as a recognition of the services of Sir Thomas Longmore, to place his portrait in the chief scene of his work. At the same time an illuminated address in an album was presented to Lady Longmore. Sir Thomas returned thanks for himself and Lady Longmore, after which the company adjourned to luncheon in the mess-room. A list of the successful candidates for commissions and of the prizemen will be found in another column.

"SUSPICIOUS" DISEASE IN SPAIN AGAIN.

A NUMBER of "suspicious cases" have recently occurred in Madrid, which some people, remembering how, at the beginning of the last outbreak of cholera, all the cases were returned merely as "suspicious," are afraid are veritable cases of that disease, especially as it is raging in Sicily at the present time, and there is a good deal of communication between Italy and Spain. The leading medical journal remarks that cholera has never been known to break out primarily in an inland town without previously manifesting itself on the coast. The idea was started that the persons attacked must have drunk poisoned milk, and the milk, or at least some milk, was sent to the municipal laboratory, where nothing more injurious than a little carbonate of soda was detected. It was then suggested that white lead might have been put into the milk in mistake for carbonate of soda. This, however, would appear to be most unlikely, and, as carbonate of lead is insoluble, detection would have been tolerably certain. Altogether there would seem to be an entire want of positive evidence to indicate the milk as the source of infection, especially as it is stated that many of the affected persons had not been in the habit of drinking milk. This is said to have been notably the case in a deaf and dumb asylum, whose inmates, together with the servants and teachers, have been amongst the sufferers. The food sold in the town has also been examined, with the usual result that a good deal of it was found to be adulterated. Still, nothing has been discovered to prove that any large quantity of

Digitized by Google

arsenic, lead, or other toxic substances capable of producing colic and intestinal disorder has been mixed with the food; so the origin of the "suspicious cases" still remains involved in obscurity, though it is to be hoped that it will not be allowed to remain in that condition, even should the malady be found to be of a zymotic character.

DEATH OF THE CROWN REPRESENTATIVE OF SCOTLAND.

THE death of Dr. Fergus is noticed in our obituary columns. It is a lamentable occurrence, of which we cannot forbear editorial notice. Dr. Fergus was a conspicuous citizen of Glasgow, a leading medical practitioner, and a much-respected member of the Medical Council. He was one of three brothers who all made their mark in our profession. His late brother John was an able physician and Professor of Medical Jurisprudence in King's College. His brother Walter died but recently, and was for over thirty years medical officer to Marlborough College. Andrew Fergus was one of those men who are invaluable in any community or body with which they happen to be associated. Cholera invaded Glasgow on two occasions, and found a spirited enemy in Fergus. He not only seized the practical points of treatment, but was one of the first to grasp the true principles of sanitation and to give them that impetus which has made Glasgow comparatively healthy. Besides the high offices he held in the profession, and in spite of his large practice, he found time to serve in the Town Council for several years, and to be a leading politician in Glasgow. He had the honour, not enjoyed so far by any general practitioner, to be chosen, in the time of Lord Beaconsfield's ministry, to represent the Crown for his Division of the kingdom.

ST. ANDREWS GRADUATES' ASSOCIATION.

THE annual meeting of this Association was held at 11, Chandos-street, Cavendish-square, on the afternoon of Tuesday, July 26th. Drs. B. W. Richardson and J. H. Paul were re-elected president and hon. treasurer respectively, the former having held office thirty, the latter twenty-eight years. The account of the hon. treasurer showed a balance of £65 16*s.* 9*d.* in favour of the Association. A contribution of twenty guineas was voted to the students of the University to assist them in founding a Students' Union similar to the well-known institutions at Oxford, Cambridge, and Edinburgh; and the Association requested and obtained permission of Surgeon-General Gordon, C.B., to print a limited number of copies of his Address on Medicine in Ancient India for distribution among the members of the Association.

THE ALLEGATION AGAINST A HOSPITAL.

ANOTHER charge against one of our large hospitals has recently been published. It is stated that a man who was seriously ill was refused admittance to the hospital, although producing an order for admission from his club doctor, and was sent in a condition of grave danger to the infirmary, where, after much difficulty, he was admitted. We have caused inquiries to be made, and find that the man was examined and found to be in a maniacal state after a fit in the street, and a club certificate was produced which said that he was under treatment for epilepsy. There was no cardiac disease; and as a man in the condition of the patient was able to be moved he was sent to the infirmary—cases of such character, unless of the greatest gravity, not being admitted to the hospital. No recent order for admission was produced, and the doctor who sent him could not have known the rules of the hospital, to the medical staff of which it is, of course, left to say when a patient is a proper case to be admitted. The friends appeared to have acted upon the suggestion of the hospital authorities, and made no objection as to removal. It is, of course, right that such complaints should be considered, but surely it is also right that the members of hospital staffs should not be annoyed in the discharge of their duties by charges which only require investigation to be disproved.

SOUTH LONDON AND THE HOSPITAL SUNDAY FUND.

MR. NELSON HARDY, in a letter to the *Standard*, complains that the south of London gets less out of the Hospital Sunday Fund than it sends. We would remind Mr. Hardy of the dictum of a great authority that "it is more blessed to give than to receive." It has been the happiness of South London to be well supplied by two large and rich hospitals, endowed generously by the liberality of men who lived long ago. Such endowed hospitals have been excluded, with general approval, from the benefit of the Fund. Should they unfortunately become dependent, like other hospitals, on casual and voluntary support, they might come to claim a share of the Hospital Sunday Fund. But it is too soon to anticipate such an unhappy state of things. The other ordinary and unendowed hospitals on the south side of the metropolis receive grants on the same principles precisely as similar institutions in other parts of London. Mr. Hardy's complaint should be fairly stated at the annual meeting of the constituents, as well as to the Distribution Committee.

THE SMOKE NUISANCE ABATEMENT BILL.

THIS Bill, of which we gave some account last week, suffered shipwreck in the House of Lords on Monday evening. The opposition took the somewhat unusual shape of an amendment, on the motion to go into committee, to the effect that before the law for the prohibition of smoke is extended to private dwellings, it is desirable that the purpose and intention of the existing Acts be more fully carried into effect either by amendment or better administration. Upon a division the amendment was carried by a small majority, and in view of the objections to which we have already referred we cannot greatly regret the loss of the measure. Our own view found fitting expression at the lips of the Lord Chancellor, who is reported to have said that although he sympathised with the objects of the promoters of the Bill, the measure itself was so ill-digested clumsy, inconvenient, and totally inoperative for the purpose for which it was designed, that he hoped it would not be agreed to.

SCENES AT EXECUTIONS.

No one can pity the despicable coward who, having murdered his victim in cold blood, crouches in horror before the scaffold on which the penalty of his crime is to be paid; but it is discreditable to our administration of justice that the execution of the last dread sentence of the law should be the occasion of a scene in which the malefactor has to be "half-dragged and half-carried by five warders" to doom, and when on the scaffold struggles so violently that the executioner has difficulty in performing his hideous task and is "quite unnerved." We cannot desire that the punishment of death—so long as it is inflicted for deterrent purposes—should be shorn of its terrors to the public mind; but we do most certainly think that there should be no room or occasion for scandal in connexion with its infliction, and it *is* a scandal that the victim should be able to recoil or resist. Electricity and the lethal chamber have been again and again suggested as alternative modes of putting murderers to death. The authorities do not, it would appear, feel justified in adopting either of these expedients.

Digitized by Google

We confess that our sympathies are with those who entertain a fear lest luxurious and easy modes of execution might deprive the gallows of the very little moral influence it at present exerts. Meanwhile, it must not be forgotten that something is due to the sentiment of humanity which is supposed to pervade that section of the nation which is not, at least overtly, criminal.

THE PRESENT AND FUTURE OF WORKING WOMEN.

WE have felt it to be our duty to draw public attention in former issues of this journal to the hard conditions which trade custom has with singular injustice assigned as the lot of very many working women. It is therefore with lively satisfaction that we notice the indications of a systematic endeavour on the part of certain representative members of the community to understand, and as far as possible to alleviate, the hardships of a class whose troubles are certainly greater than its complaints. Mr. Walter Besant, in a recently published letter, proposes the meeting of a conference towards the end of the present year to discuss the whole question of female labour, and a committee, including several well-known names, has already been appointed to carry the scheme into execution. Overwork and underpay, it has been truly said, are terms which briefly describe the purport of the market regulations under which women in the present day find employment. The inordinately long working period, the wage, far too often absurdly inadequate to the effort, which it pays, the evil of close and ill-ventilated workrooms, the absence of necessary conveniences, and the very faulty dietetic arrangements, each of them a common grievance in the world of warehouse life, will, we cordially hope, receive due consideration in the deliberations of the coming congress. It is, however, most necessary to the fruitfulness of its praiseworthy endeavours that the body of evidence bearing upon the condition of working women, in its moral, social, and monetary aspects, should be as full as inquiry can make it within the time allowed for investigation. We would therefore strongly advise the many men and women whose daily visitations bring them in contact with the industrious poor to collect and forward all possible information bearing upon this important subject to Mr. Besant, at the Adelphi Hotel, Adam-street, Strand, W.C.

GASTRIC MOVEMENTS.

DR. GRUNDZACH reports in a Polish medical journal some cases of "atrophic catarrh" of the stomach where the glandular elements were considerably atrophied, and where the gastric juice existed only in very small quantity, and contained scarcely any hydrochloric acid. Notwithstanding this, the gastric movements were normal, so that the food did not remain longer than usual in the stomach, thus [illegible], according to the author's view, that the acidity of the contents of the stomach is not, as many physiologists teach, the cause of the gastric movements.

THE DRAINAGE OF MELBOURNE.

The necessity of maintaining the purity of rivers is beginning to be felt by some of our colonial fellow-subjects. Steps, for example, are being taken in Melbourne to improve the condition of the Yarra Yarra, which, it seems, is made to receive the whole of the sewage of the city as well as the refuse of numerous manufactories situated on the banks of the stream. The *Age* suggests the adoption of a system of drainage similar to that in existence in London; but we venture to hope that the citizens of Melbourne will exercise sufficient intelligence to enable them to avoid the mistakes which Londoners have made in respect of sewage disposal.

DR. KLEIN ON THE GROUSE DISEASE.

OUR contemporary the *Field* published in its issue of July 23rd a report by Dr. Klein of an inquiry he has been undertaking into the nature of the grouse disease, which has been prevalent on the moors of Ayrshire and Cumberland during this spring and summer. He visited several moors, and examined a large number of birds the subjects of the disease. The most constant anatomical changes were congestion of some parts of the intestines, great congestion and discolouration of the liver and kidney, and in some cases also of the lung. In some cases there was peritonitis. In all the birds taeniæ (T. calva) were present in the small intestine, in some in great numbers; and in one or two instances there was perforation of the bowel, other than from the effects of shot. Of the three views hitherto advanced concerning this disease—viz., that of Dr. Farquharson that it is of the nature of an infective disease, that of Dr. Cobbold that it is due to the strongylus pergracilis in the intestine, and a view advanced sixty years ago that it is due to penetration of the intestine by taeniæ,—Dr. Klein was at first disposed to accept the last, for he found no evidence of pathogenic microbes in the organs and tissues, and none of the birds examined contained the strongylus, whereas in all taeniæ occurred. But he was soon led to abandon this idea, seeing that the tapeworms occur in grouse which have not died of the disease, and that the presence of these parasites would not account for the diseased condition of the liver. Accordingly, he submitted the liver to microscopical examination, and detected in suitably prepared specimens certain corpuscles about two to four times the diameter of the liver cells. These bodies occurred in large numbers, and were of various shapes—cylindrical, spindle-shaped, irregularly elongated, or furnished with processes. They were nucleated protoplasmic bodies, and were apparently of the type of fungi known as plasmodia. In some of the larger branches of the veins of the liver forms were met with resembling spores of plasmodium. The presence of such fungi in the blood-vessels of the liver, and perhaps of the intestine also, would sufficiently account for the morbid changes detected; but Dr. Klein reserves his final conclusions until these bodies have been studied in the fresh and living state, and their distribution in the diseased animals and the mode of entrance into their bodies have been ascertained.

COCAINE INTERNALLY.

DR. L. FREY, of Békés, having as a patient a young woman who had mitral insufficiency and hypertrophy of the heart associated with hyperæsthesia of different parts of the body, which caused extreme irritability of the stomach and constant vomiting, so that for some days she had scarcely twenty minutes' intermission, tried digitalis, opiates, ice, cold applications, &c., but without any effect. He then determined to try cocaine internally. He gave three-quarters of a grain dissolved in water, which was followed by a cessation of the attacks of vomiting for two hours; another dose gave the patient six hours' rest, after which a violent attack of vomiting came on. The third dose stopped the vomiting altogether, after which all the other symptoms from which the patient suffered rapidly improved.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Loncq, formerly Professor of Medicine in the University of Utrecht.—Dr. Lubanski, formerly of Val-de-Grâce, the author of the feuilletons in *L'Union Médicale*, signed with the *nom de plume* "De Bray."

Digitized by Google

THE CROWN PRINCE OF GERMANY.

THE base of the growth having become slightly more elevated at one point, Dr. Morell Mackenzie has thought it desirable to apply the electric cautery at this spot. For this purpose his Imperial Highness came to London on Tuesday, and an application was made the same day. The result was found to be entirely satisfactory on the following day, no inflammatory reaction having been set up, and the Crown Prince returned to Cowes on Thursday. The general health is excellent, and the voice very good.

MEDICAL HONOURS.

ON the 2nd inst. the Queen held an Investiture of the Orders of the Bath and St. Michael and St. George at Osborne. Amongst others the following Knight Commanders of the Order of the Bath were introduced into the presence of the Sovereign who conferred upon them the honour of Knighthood, and invested them with the insignia of the respective divisions of the second class of the Order into which they have been admitted—viz.: Military Division: Surgeon-General John Harrie Ker Innes; Inspector-General of Hospitals William Mackenzie, M.D., Indian Medical Service; Inspector-General of Hospitals and Fleets James Jenkins, Royal Navy. Civil Division: John Simon, Esq., M.D., late Medical Officer, Privy Council Office; Arthur Mitchell, Esq., M.D., Commissioner in Lunacy in Scotland.

THE CHOLERA.

THERE fatal cases of cholera are officially reported as having occurred this week at Malta. The authorities appear to be doing what they can to prevent the spread of the disease by removing suspicious cases to the lazaretto, and by thoroughly cleaning out the houses. In consequence of the existence of the malady on the island, quarantine is imposed at Gibraltar and Madrid on vessels arriving thence. At Catania the disease during the last week has not, it appears, diminished in violence, from fifteen to twenty deaths being recorded daily. The disease has extended to the prisons and monasteries. In the provincial towns (especially at Anderno, Paterno, Francofonte, and Cerami) the epidemic seems on the increase, whilst more favourable reports come from Syracuse and Calabria. According to a recent telegram from Bombay, cholera prevails to a serious extent at Peshawur, where 300 deaths occurred from the disease during July.

THE LETTING OF UNHEALTHY HOUSES.

IN one sense we are glad to find that actions for damages against landlords for letting houses in an unwholesome state are on the increase. Recently a case has been tried before Mr. Justice Cave at the Maidstone Assizes. The plaintiff alleged that a house had been let to him on the assurance that the sanitary arrangements were perfect, but that in consequence of the drain defects blood-poisoning and other illness affected his family, necessitating abandonment of the house, medical fees, and resort to the seaside for convalescence. The peppermint test as applied to the drains revealed leakage into the house of sewer air, and both as to this point and the sickness a number of witnesses were called. The defendant, himself a builder, was ready with a large number of witnesses to prove the precise contrary, but in the end the jury returned a verdict for the plaintiff for £142 and £60 damages. On behalf of the defendant notice of appeal was given, and if the appeal is heard we may have some decision as to the precise responsibilities in regard to details of house sanitation, both of landlords and tenants, which will be of material value as a precedent.

UNIVERSITY COLLEGE, LONDON.

DR. GRAILY HEWITT has been appointed by the Council of University College Emeritus Professor of Obstetric Medicine in the College and Consulting Obstetric Physician to the Hospital. Dr. Angel Money, Mr. Bilton Pollard, and Dr. H. R. Spencer have been respectively elected assistant physician, assistant surgeon, and assistant obstetric physician to University College Hospital.

COMMON LODGING-HOUSES.

THE Government of New South Wales have under consideration the question whether common lodging-houses shall be administered by the police authority or by the Board of Health, and no doubt good reasons can be shown for placing this duty upon either body. There is something to be said in favour of entrusting this supervision to the police, seeing that common lodging-houses are largely resorted to by the criminal class. This argument was urged at the time houses of this nature in London were the subject of legislation, but underlying this reason was the undesirability of entrusting the power of control to existing sanitary authorities. The ventilation, lighting, warming, and general condition of these premises, and, above all, the dealing with cases of infectious disease, can more conveniently be undertaken by sanitary officials, and we may hope that the uncertainty of administration that existed in London may not in Australia be found to be sufficient reason for removing this branch of sanitary work from its natural position.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—The new Laryngological Clinic under Dr. Fraenkel is now in full work, and is attended by a large number of patients. It is fully recognised by the authorities as a place for study, being replete with every instrument and convenience.

Jena.—Dr. Theodore Ziehen has joined the Medical Faculty, his inaugural dissertation being on "Sphygmographic researches on lunatics."

Lille.—M. Debierre, *agrégé*, has been transferred from Lyons, to replace M. Assaki.

Madrid.—Dr. Don Benito Hernando, of Granada, has been appointed to the Professorship of Therapeutics.

Marseilles.—M. Rietsch, *Docteur ès-Sciences*, has been appointed to the Professorship of Chemistry.

Montpellier.—The candidates for the chair of Therapeutics have been arranged in the following order:—1, M. Pécholier; 2, M. Hamelin.

Poitiers.—M. Lachaize, Professor of Anatomy, has been transferred, at his own request, to the chair of Physiology, M. Buffet-Delmas will now lecture on Anatomy.

DURING the present summer session there have been 8512 medical students in the universities of the German Empire, who have been distributed as follows:—Berlin, 1140; Bonn, 371; Breslau, 390; Erlangen, 262; Freiburg, 433; Giessen, 119; Gottingen, 248; Greifswald, 528; Halle, 330; Heidelberg, 240; Jena, 213; Kiel, 292; Konigsberg, 270; Leipsig, 713; Marburg, 302; Munich, 1186; Rostock, 121; Strassburg, 221; Tubingen, 272; Wurzburg, 861.

COMPLAINTS have reached us as to the method of conducting the recent examination for the diploma in Public Health at Aberdeen University. We refrain from comment until we have made thorough inquiries.

A BACTERIOLOGICAL INSTITUTE is to be established at Tiflis. Some £500 is available for the purchase of instruments.

Digitized by Google

THE death, on the 17th ult., from pneumonia, of Dr. Joseph D. Hutchison of Brooklyn, is announced. For several years Dr. Hutchison served as Health Commissioner of Brooklyn, and he was also the author of several works and papers on Surgery. He was a delegate to the International Medical Congress held in London in 1881.

THE commencement of a new Spanish journal to be devoted to military medicine and surgery is announced. The title is *La Revista de Sanidad Militar*. The editors are Drs. Aycart and Quintana. A Spanish naval medical journal is already in existence.

THE Commission sent by the Italian Government to Catania with a view to examining on the spot the best means of combating the cholera epidemic, has just been reinforced by Professor Mariano Saluzzo.

THE Italian Government has just created a corps of sanitary police, and has placed at the head of the new body, Dr. Pagliani, Professor of Hygiene in the University of Turin.

AT the ordinary weekly meeting of the Cardiff Board of Guardians on the 30th ult., Dr. Paine announced that the epidemic of small-pox recently raging in that town had practically passed away.

THE twelfth Congress of the Italian Medical Association will be held this year at Pavia, from the 19th to the 24th of September.

Pharmacology and Therapeutics.

AN IMPROVED CAUSTIC PASTE.

DR. JULES FELIX, of Brussels, having found existing caustics unsatisfactory from the great pain which is caused by their application, from the difficulty of limiting their action precisely to the part desired, from their deliquescence and from various other causes, has devised a form of caustic paste which he has been using for some time past with the best results. It does not cause severe pain or set up any general reaction; the eschar is hard and well defined, so as to be easily detached. It is also a powerful antiseptic and haemostatic. It is not deliquescent, but keeps its consistence, which is that of putty, well, and so lends itself easily to manipulation. The hands should be wetted when applying it. They are not in any danger of being acted on. The paste is allowed to remain for from six to twenty-four hours according to the amount of eschar which it is desired to form. The formula for the paste is as follows: Mix in a mortar the following substances in powder:—Starch, 37 grms.; wheat flour, 112 grms.; bichlorides of mercury, 1 grm.; dry chloride of zinc, 110 grms.; iodol pure, 10 grms.; croton chloral, 10 grms.; bromide of camphor, 10 grms.; crystallised carbolic acid, 10 grms. Then add gradually a sufficient quantity of distilled water to form a homogeneous paste without lumps of the consistence of putty. This paste will keep an indefinite length of time.

BORATE OF AMMONIUM IN PHTHISIS.

Borate of ammonium has been found by Professor Lashkevich of great value in phthisis. Internally he gives five grains three times a day in solution, either alone or combined with codeia, hyoscyamus, or other sedatives. This he finds produces a marked effect on the expectoration, and in some cases where the affection had only reached an early stage a distinct diminution of the pyrexia was observed. The solution was also employed with advantage as an inhalation (in the form of spray?), reducing the expectoration and alleviating irritating and painful conditions of the mouth and throat.

ALKALINE MERCURIAL SOAP AS AN ABSORBENT.

Dr. Svetukhin, chief of Professor Lashkevich's clinic in St. Petersburg, in some therapeutic notes contributed to the *Russkaya Meditsina*, mentions that various preparations have been recently employed in the wards for the purpose of promoting absorption of pleuritic effusion. Iodine ointment is too mild and too slow in its action to answer the purpose, and the odour of iodoform ointment is so strong that it interferes too much with the comfort of the other patients, and so is found to be unsuitable for hospital practice. It was found that iodine ointment could be advantageously supplemented by soft soap (sapo kalinus viridis) inunctions, or by rubbing in unguentum hydrargyri. The most valuable of all applications for this purpose was, however, found to be a preparation called sapo kalinus hydrargyrosus, which is made by mixing in certain proportions metallic mercury, unguentum hydrargyri, caustic potash, and olive oil, so that the resulting soap contains a third of its weight of mercury, the unguentum hydrargyri of the Russian Pharmacopoeia containing half its weight of mercury. This is agitated with hot water so as to form a good froth and lightly rubbed into the skin. It has the advantage over ung. hydrargyri in being much more easily rubbed in, in not irritating the skin and thus causing eruptions, and, lastly, in not so rapidly setting up stomatitis or salivation. From half a drachm to a drachm of this mercurial soap is used for each inunction. After from six to ten applications some diminution may be detected in the effusion, and after twenty inunctions the whole is usually found to have disappeared. Of course, favourable results can only be looked for in cases of simple effusion; they cannot be obtained in empyema.

CYANIDE OF ZINC IN CARDIAC AFFECTIONS.

Cyanide of zinc exerts, according to Professor Lashkevich, a beneficial effect on some cardiac cases which cannot be obtained by other means. In cardiac neuroses it acts quickly and certainly. Palpitation, want of rhythm, and pain in the region of the heart are quickly affected, sometimes indeed cured, by this drug. The dose is from a tenth to an eighth of a grain three times a day. Similar beneficial effects are produced when there is organic cardiac disease. The regulating action of cyanide of zinc in valvular insufficiency is less marked than its effect on cardiac neurosis; nevertheless, there were cases in the wards where it acted better than other cardiac remedies, as digitalis, convallaria majalis, adonis vernalis, &c. In this respect it acted particularly satisfactorily in cases where other remedies could not be given without producing derangement of the gastro-intestinal system. Here it improved the action of the heart, thus increasing the secretion of urine, moderating the pulse, and diminishing the dropsy due to irritation of the gastro-intestinal canal. In a case of nervous palpitation with hysterical anuria, cyanide of zinc diminished the palpitation, and at the same time caused the secretion of urine to recommence.

A NEW SOURCE FOR BORAX.

From some analyses made by Señor Emil Eisele of Valparaiso, and by Mr. J. Clark of London, of several samples of crude Chilian borax, it would appear that Chili is capable of producing at least as good borax as California, the quality being equal to a good deal of that which comes from Italy. The attempts which are being made to open up a borax industry in Chili would therefore seem likely to prove successful.

CARBOLATE OF MERCURY IN SYPHILIS.

Dr. Schadeck has employed carbolate of mercury both internally and hypodermically in syphilis with remarkable success. He gave it in thirty-five cases in the form of a pill without finding it give rise to any gastric disturbance. The formula was—R Hydrargyri carbolici oxydati, 3 dr.; pulv. glycyrrh. q.s. ut f. massa pil. ex qua form. pil. No. 60; from two to four pills daily after food. This preparation was originally used by Gamberini in 1886. Dr. Schadeck also employed the carbolate of mercury in ten cases in the form of hypodermic injections, which he administered in the glutal region, causing the needle to penetrate the muscles deeply. The liquid used was a mucilage containing 2 per cent. of carbolate of mercury in suspension. In this way his results were as satisfactory as when the preparation was given by the mouth.

BRITISH MEDICAL ASSOCIATION.

FIFTY-FIFTH ANNUAL MEETING,
HELD IN DUBLIN, 1887.

THE annual meeting was held this year in Dublin, and commenced its sittings on August 2nd. When contrasted with similar gatherings, it must be regarded as having been an unqualified success. Although the real work of the Association did not commence until Tuesday, yet Monday was a busy day at the reception-room, which was crowded by visitors from an early hour.

On Tuesday, at 11.30 A.M., in the Examination Hall, Trinity College, the first general meeting was held. Dr. Withers Moore, the out-going President, referred to the love and veneration felt towards Dr. William Stokes, who was present at the previous Dublin meeting. He could not have believed that the prosperity of the Association could have increased so rapidly. He thought they should not depend too much on their excellent representative Council, but principally on the professional ardour and the goodwill of individual members. He had now the pleasure of introducing their distinguished President, Dr. Banks, and he offered him his sincere wishes for a happy and prosperous year of office. Dr. Banks then took the chair, and offered on the part of the Branch Council a most cordial welcome to the members of the Association. Mr. Wheelhouse of Leeds moved that the thanks of the Association be offered to Dr. Withers Moore, and that he be elected a vice-president for life. Sir Thomas Crawford seconded the resolution and spoke highly of the courtesy of Dr. Withers Moore. Dr. Banks put the resolution, which was passed by acclamation. Dr. Moore responded in suitable terms.

Sir WALTER FOSTER moved the adoption of the Report of Council, of which the following is an abstract:—

In response to an invitation from the medical corporations, colleges, and the profession in Dublin, the Association have again the privilege of holding its annual meeting in Dublin, a city not less renowned for the zeal and ability of its scientific workers than for its genial hospitality and the charm of its social life. The Association continues to increase both at home and abroad, and at present 400 new members await the completion of the formalities necessary for their due election. The financial condition of the Association is satisfactory, and the investments amount at present to £17,566. The Parliamentary Bills Committee has been largely occupied with the question of the abolition of relative rank and its consequences to army medical officers, and has determined to use its best endeavours to obtain such a distinct acknowledgment of their rank as shall be satisfactory. The Committee of Medical Defence has felt itself unable to recommend the Council to lend the support of the Association to the proposed "British Medical Defence Society." The Scientific Grants Committee has made grants to the amount of £345, of which £63 8*s.* 10*d.* has been returned unexpended. The Middlemore Prize for the best essay [illegible] in Ophthalmic Science" has been equally [illegible] Messrs. Berry and Frost; and the [illegible] to Dr. Cory for an investigation as to the communicability of syphilis in vaccination. As regards the payment of the travelling expenses of the [illegible] representatives on the Council of the Association [illegible] attending meetings in London, the Council have approved of the following resolution:—That in the opinion of the Journal and Finance Committee it is essential for the welfare of the Association that a sum of £2000 should be invested out of the surplus every year, and that the payment of the expenses of members of the Council should be by fees as follows: members residing within 100 miles of place of meeting, one guinea; over 100 miles, two guineas; over 250 miles, three guineas; and over 400 miles, five guineas. [illegible] spoke of the present meeting as likely to [illegible] of the Association, and referred to the loss they had sustained by the death of Dr. Chadwick, whose place they could not well fill. [illegible]

An amendment was moved to the adoption of the report by Dr. STRANGE, who, although a member of Council and an ex-president of the Association, spoke against the payment of representatives. On several occasions it had been brought forward and regarded as uncongenial to the spirit of the Association, and quite foreign to their feelings. The Branches had been asked their opinion, but not the Association directly. He looked on the proposal to pay the representatives as a new departure, and one which should not be taken. It would also, if adopted, cause enormous expense.

Mr. HOLMAN, in a few words, seconded the amendment.

Mr. FITZPATRICK thought the payment of travelling fees only as a desirable proposal, and was of opinion that it was the object of the present Council to try to keep out the provincial members of Council.

Mr. HART stated that, on the contrary, the Metropolitan Branch were in favour of representatives being paid.

Dr. JOHN INCE thought payment was objectionable, and that a mercenary spirit prevailed too much among the profession.

Dr. CHARLES DRYSDALE spoke in favour of provincial representatives being paid.

Mr. HART said that the opinion of the Council had been taken three times, and they objected to it; on the fourth occasion they relented, and a vote of the Branches was taken on the subject.

Mr. JACOB believed that the interests of representatives of provincial Branches should be considered in the matter, as, practically, the management of the Association was in the hands of the London men.

Mr. WHEELHOUSE said that although he should not feel degraded by taking his fare, yet felt it might well be spent on other objects of usefulness.

Mr. THOMPSON (Omagh), as a provincial surgeon, also spoke against the payment of representatives.

The amendment was carried by a large majority—57 to about 12—and then put as a resolution.

Mr. FITZPATRICK moved as an amendment that first-class fares should be paid, which was lost by a large majority.

The meeting adjourned for an hour, and on re-assembling,

Sir W. FOSTER moved, "That the best thanks of the Association be given to Mr. N. C. Macnamara for his able services as treasurer during the past three years, and for the great interest he had shown in the welfare of the Association, and that he be elected a vice-president for life."

This was seconded by Sir THOMAS CRAWFORD, K.C.B., and passed unanimously.

Mr. MACNAMARA said it had given him much pleasure during the past three years, as the work was congenial; but he thought all the credit was due to Mr. Fowke, who was always ready in the interests of the Association.

Professor GAIRDNER moved that Mr. Holman be appointed treasurer for the ensuing three years, which was seconded by Dr. MYRTLE, of Harrogate, and carried unanimously.

Mr. HOLMAN duly returned thanks.

Mr. HART moved the Parliamentary Bills Committee's Report, and said with regard to the army medical officers, the committee had received the thanks of many hundreds of the medical officers for what they had done in their behalf.

Mr. SIBLEY seconded the adoption of the report.

Sir THOS. CRAWFORD, K.C.B. (Director-General of the Army Medical Department), regretted to find fault with the action of the committee. He promised that while he had a connexion with the medical department of the army he would do everything in his power to bring its officers into harmony with the civil members of the profession. In January last certain alterations had been made in the pay warrant, and amongst these changes was one which included the whole staff of the army. Statements had appeared in the *British Medical Journal* to the effect that the new Warrant had deprived medical officers of the only rank they held in the army. Week after week the statement was reiterated that the only rank which army medical officers possessed had been abolished. He maintained that this was not so, and that the Queen's Commission issued to every officer showed it. He read the terms of the commission which surgeons held in the army, and pointed out that there was no reference in it to relative rank. The Secretary of State for War had written that the new Warrant had not affected the rank of any medical officer in the army. Relative rank, Sir Thomas Crawford stated, was not the only rank the medical officer possessed, and he could not agree in the statements made regarding relative rank by the *British Medical Journal*, the tendency of the articles in that *Journal* being to mislead the public and the army at large. He believed that army

Digitized by Google

medical officers had not lost, but rather gained, by the late Warrant. All these changes in the working of the Army List had been done by himself, and not by the Secretary of State. He maintained that the army medical officers had not lost anything, but the *Journal* had stated the reverse. He thought it right to say that, as regards the making of complaints by those who believed they had a grievance, no man's mouth was shut, and anyone could lay his grievance before his chief, or even bring it before the Secretary of State, without being in danger of being treated unjustly. Mr. Hart had addressed the medical officers of the army asking for answers to be filled up, treating it as a confidential document, and promising to publish only an analysis of the returns sent in. He thought that the titles suggested for army medical officers by the editor they had no real claim to, and he regarded those titles as a degradation.

Dr. JOHN INCH, as a retired surgeon-major of the Indian army, thought the subject of relative rank was rank rubbish, and trusted the editor would at once extinguish the disagreeable subject. A medical officer would be always ranked according to his own medical and professional position.

Deputy Surgeon-General JOYNT thoroughly endorsed all that Sir Thomas Crawford had said.

Sir THOMAS CRAWFORD then proposed as an amendment that the paragraph on relative rank be omitted from the report, and referred back to the Council for reconsideration.

Dr. HAUGHTON approved of the matter being referred back for consideration. When will it come on again?

Sir THOMAS CRAWFORD.—In about twelve months.

Mr. HART.—Oh no; it will come on at the committee meeting in October.

Dr. HAUGHTON.—Then let it go back.

Mr. HART said that the whole of the Medical Department of the army was boiling with discontent.

Sir THOMAS CRAWFORD rose to order. There was not, within his knowledge, a single representation to any of the authorities to such an effect.

Mr. HART said that the opinions stated there that day were the opinions of an enormous majority of the medical officers of the army. When Sir Thomas stated that he had no representation to that effect officially, it only proved that the representations were not officially made to Sir Thomas Crawford. If any officer individually made such a complaint it would not hasten his selection for promotion.

Sir THOMAS CRAWFORD said the editor of the *British Medical Journal* was not justified in making such a statement as that. There was no justification for making such a statement about his (Sir Thomas Crawford's) management of his department, and to say that officers were "selected" was wholly unwarrantable.

Mr. HART said Sir Thomas took a wrong view of his observations. What he (Mr. Hart) said was that the medical officers of the army and the combatant officers were under this disadvantage—that if they felt that they had a grievance and held views which were known to be held in disfavour by the heads of their department, they were not allowed to make any collective statement, and if they individually made statements, rightly or wrongly, they felt that they were doing themselves an injury. The Secretary of State for War in the House of Commons refused to allow the medical officers to make a collective statement, and the Parliamentary Bills Committee of that association had done right in allowing the officers to express their opinions, which collectively they dare not do. He (Mr. Hart) considered it very disadvantageous to the service that these opinions should be given publicity to, and for weeks he refused to insert any letters on the question. The letters he received, however, grew in number, and telegrams collectively from officers, saying, "This station is in a state of the greatest discontent; the answer of the Secretary for War is causing the greatest dissatisfaction," were daily received [illegible]. It was only the other day that he received from [illegible] telegram signed by 200 medical officers, and enclosing a very handsome cheque, which he did not ask for, "to defray the expense of circulars to take individual opinion." [illegible] been done was done with the sanction and by the advice of the most eminent men in the army, and their [illegible] to obtain the wishes of the service. With this [illegible] had framed a circular asking each officer which of [illegible] he would approve of. One of the gentlemen [illegible] that the agitation proceeded from a low [illegible] visiting [illegible]

Sir THOMAS CRAWFORD explained that this expression was used in a letter which he had read, and was not used by him personally.

Mr. HART said those who were moving in the matter were men occupying the most eminent positions.

Mr. MACNAMARA said he was in the army for many years, and never had the slightest hesitation in approaching the head authorities and making known any grievance he had. The circular was clearly an incitement to the officers of the British Medical Service to insubordination. (No, no.) The British Medical Association was tempting them to commit an act which they were afraid to commit in any other way. Why don't they go to Sir Thomas Crawford or the Secretary of State? As an officer of long-standing in the service, it went very much against his feelings to hear that the British Medical Association should in any way countenance action of this kind.

Sir THOMAS CRAWFORD read an annotation to a communication which appeared in the *British Medical Journal* of May 7th, and which urged that the grievances of the service should be taken up by the colleges and other schools, and that Mr. Hart would give all information to those requiring it.

Mr. HART.—Hear, hear.

Sir WALTER FOSTER said he had been very much struck by the very able statement of Sir Thomas Crawford. He was also struck by the fact that three retired medical officers had got up to support him. From this they were justified in saying that the universal discontent referred to does not exist.

Mr. HART.—I will not object to the matter being referred back, provided that is not regarded as a vote of censure on the committee.

Sir THOMAS CRAWFORD said he had endeavoured all along to convey that he intended no censure.

The report was, after some further conversation, referred back.

Dr. NORMAN KERR moved that the Report of the Committee for Legislative Restriction for Habitual Drunkards be received and adopted, which was seconded by Dr. E. P. THWING of New York, and adopted.

The meeting then adjourned until 8.30 the same evening, when the President delivered his address. In this Dr. BANKS, following the example of many of his predecessors, confined himself to matters of local interest, particularly those connected with the Dublin medical institutions, and the changes and improvements which twenty years have brought about. He commenced by giving a historical sketch of the connexion of medicine with the Dublin University, a brief account of the College of Physicians and the careers of some of the most famous of its early Fellows, the Dublin School of Medicine, and the Royal University of Ireland, and concluded by defending the Association from a charge which had been brought against it, and others of a cognate character—namely, that its members met chiefly, if not altogether, for amusement and recreation. To this he gave an emphatic denial, for labour took the first place, and then came recreation and social intercourse, the value of which, he admitted, was highly appreciated. Virchow, in his address at the last meeting of the Association of Naturalists and Physicians at Berlin, after pointing out that the greater part of the time at their disposal should be devoted to earnest work, said: "Aber nach der Arbeit ziemt es zich wohl der Erholung und dem freundschaftlichen Verkehr ihr Recht zu lassen." The original statutes of the Association laid it down that the chief object of the meetings was to make the members personally known to each other. No one proclaimed this with more force than Alexander von Humboldt in opening the meeting fifty-eight years since. He said: "Die Hauptzweck dieser Gesellschaft ist die personliche Annäherung derer welche dasselbe Feld der Wissenschaft bearbeiten."

At the conclusion of the address Sir WALTER FOSTER suggested that some outstanding business should be transacted before the meeting separated.

A vote of thanks to the President was proposed by Dr. HAUGHTON, seconded by Sir SPENCER WELLS, and adopted with acclamation. After some further discussion, which resulted in nothing, the Congress adjourned.

At the second general meeting of members, held on Wednesday, the report of the Council for the place of the annual meeting for 1888 was under consideration, and further to report the election of the President of Council. To the latter office Mr. Bridgewater of Harrow has been elected, and the invitation from Glasgow to hold the annual

Digitized by Google

meeting for 1888 has been accepted. Professor Gairdner had been elected President-elect of the Association. The following motion was adopted with acclamation:—"That the cordial thanks of the Association be given to Sir Walter Foster, M.P., for the able way in which he has presided over this Council during the past three years, for his great attention to the affairs of the Association, and for his advocacy of the various measures in Parliament, whereby the influence and power of the Association and the medical profession has been materially advanced, and that he be and is hereby elected a vice-president for life."

The address in Medicine was then delivered W. T. Gairdner, M.D., F.R.C.P., Professor of Medicine in the University of Glasgow, an abstract of which appears in another part of our present issue.

THE PAIL SYSTEM AT MANCHESTER.

THE English system of utilising water as the motive power for conveying away the sewage of towns has never met with very unanimous or enthusiastic approval abroad. For many years, in France especially, a fierce contest has raged between those who would imitate the English example and those who, on the contrary, maintain that a sewer is of more danger than use. As yet it is only a distant echo of the dispute that reaches our shores. We receive scientific deputations who come in the name of foreign municipalities and examine our sewers; and, as often as not, return with the impression that the system would in nowise be applicable to their country. We read to-day that a very narrow majority of the Paris Municipal Council is in favour of the "tout à l'égout"; and to-morrow we shall be informed that by an equally narrow majority this, the English system, has been condemned. The same is the general result of the debates at the Société de Médecine Publique et d'Hygiène Professionelle. But in England this neck-to-neck race between the French advocates and opponents of our system of water drainage excites but little attention. Now, however, there are evident signs of awakening. Our population is increasing so rapidly that it becomes daily more difficult to know how to dispose of our sewage without contaminating our water supply. The latent feeling that a wicked waste is perpetrated by the unscientific course of throwing into rivers and the sea that which should be utilised to fertilise the soil has recently found voice. Dr. G. V. Poore, in a most powerful address delivered at the anniversary meeting of the Sanitary Institute of Great Britain, has put the question in a vivid light. So strong is this indictment of the present sewer system, that the first impression produced is the desire to know what remedy is proposed, rather than a disposition to challenge and discuss the necessity of any alteration. Dr. Poore advocates small allotments and the utilisation of household refuse and soil as garden manure. This he has tried practically and successfully; and it might be applied in new districts where the population does not exceed 100 to the acre or 50,000 to the square mile, allowance being made for roads, &c. Unfortunately, it is not everyone who has the time or taste for gardening; and, however perfect in theory, it would scarcely be safe to trust every household to bury its own soil, even though this were to produce 784 lb. of potatoes per annum for each of twenty cottages built on one acre and containing altogether 100 inhabitants.

Practically, when dealing with towns there are two methods to suggest in the stead of sewers—namely, pneumatic drainage or the pail system. For the former the best illustrations are the Berlier system as applied to the west-end of Paris, and the Liernur system of Amsterdam. In England, we have at Manchester a very elaborate application of the pail system, and under the present circumstances it will not be out of place to briefly review what has been done in this respect. For this purpose our representative proceeded to Manchester, and with the courteous assistance of Sir Joseph Heron, the town clerk, and Dr. Leigh, the medical officer of health, was able to see in all its details the application of the pail system.

It was in 1868 that the Health Committee of the Corporation of Manchester was appointed to carry out the pail system. At that time the death-rate amounted to 33 per 1000 inhabitants. The city then contained 60,000 open cesspools, which overflowed into the sewers. In some cases there was only one closet for a dozen houses. In other respects the town was in an equally benighted condition; there were no fever hospitals, no means of disinfection, no public baths, no slaughterhouses, &c. We now find that what is termed the city of Manchester has a population of 376,895, and a floating day population of 150,000 men, who come in from the neighbourhood for the transaction of business. For the accommodation of these half-million people there are 66,000 dry ash closets, 40,000 dustbins, 11,000 waterclosets, 50 public urinals, and 4000 middens, besides the conveniences provided at the railway stations. The contents of the closets and urinals flow through the drains and sewers into the little stream called the Irwell, which divides Manchester from Salford. The pollution of the Irwell, taken in connexion with the Manchester Ship Canal that is about to be built, opens out a complex question which cannot be touched upon at present, though it will demand the earnest attention of both sanitary and financial reformers.

To remove the pails containing the dry ash and soil and the metallic dustbins a staff of 240 men with 130 horses has to be maintained. The horses travel some fifteen miles a day. Each van contains twenty-four pails, and weighs, when empty, 38 cwt., and when the pails are full the average weight is 56 cwt. The closet contents and domestic refuse collected by the vans amount to about 3000 tons per week. It must, however, be noted that Manchester is a town that is especially adapted to this method. It is a town of small cottages spread over a very large space. In the central districts, where there are very large houses several stories high and closely packed, the pail system has not been applied, and it has been necessary to tolerate no less than 11,000 waterclosets for the accommodation of these more luxurious dwellings. As compared with such towns as London, the example of Manchester could only apply to outlying districts where there are cottages or villas with gardens. The Manchester pail-closet is placed at the further extremity of the back yard of each cottage. There are generally two closets back to back, and between them is the movable receptacle for the house refuse. The ash or cinder is thrown on a rough sieve, so placed that the larger cinders fall into the dustbin while the fine ash goes into the pail placed under the closet seat. A little door between the two closets opens out into a narrow passage running behind the cottages. Along these passages the scavengers or night-soil men come to fetch the pails. By opening the one door they are able to withdraw the two pails and the dustbins, and replace them by empty, clean receptacles. The one passage does of course, for two rows of houses; and the scavengers, having emptied two closets to the right of the passage have two similar closets to empty on the left side. Thus, the closets stand in groups of four along the passage that divides the back yards of the rows of cottages. Under this passage also is often placed the drain for slop and washing water, so that it is not necessary to pass pipes through the houses to reach the street sewer for the purpose of carrying away rain or slop water. Each closet has a ventilating shaft that is carried to the roof of the cottage.

We visited a considerable number of these pail closets, some in the poorest quarters of Manchester, and most readily acknowledge that they were remarkably free from bad odours. In London, in poor quarters, it will be found that the closets are often out of order. The flushing apparatus will not work; very frequently there are no means whatsoever of flushing provided; at other times the trap is broken or stopped up, and, from one cause or another, offensive odours arise. In Manchester the worst we saw was a little superficial dirt, the evidence of carelessness, but nothing that could endanger health by the introduction of unknown quantities of sewer air. It is true that the drain in the passage behind Beaumont-street does not seem to be properly laid. The central part of the passage is at a lower level than the two extremities, and here the water had overflowed through the gullies. Unpleasant pools of stagnant water rendered it difficult to pass, and the inhabitants assured us that this was of frequent occurrence. The backyard of one of the cottages was also in a filthy state. It required re-paving; dirty water and soil had accumulated on the ground; but, with the exception of missing flagstones, there was no structural defect. The fault lay with the inhabitants, while the overflow from the drain had no connexion whatever with the pail system. The pail, it seems, is not likely to soon get

Digitized by Google

out of order, or be misused. It is removed once or twice a week, and thus no accidents can long remain unnoticed. With waterclosets grave and dangerous defects may exist which might not be detected for months or years. Altogether, so far as the risks of bad drainage are concerned, one would certainly prefer a Manchester to a London slum. The dirt, such as it is, is superficial dirt, and the odours are those of the house itself, and not of the sewers that come from great distances and receive specific germs from a vast area. One structural defect should not have been sanctioned. In several instances the ventilating shaft from the closets was built of bricks and conducted upwards within the wall of the cottage. Considering that bricks are highly porous, and that rooms are hotter inside than out, a certain amount of air from the shaft would be drawn through the bricks into the rooms. Unconsciously persons may sleep with their faces right against the porous ventilation shaft of the closet. Under such circumstances, it would be better not to have any shaft at all. The emanations of the closet should ventilate into the open, at the far end of the back yard, instead of being conducted towards the house through a porous brick shaft. Such shafts, if necessary at all, should be run up outside the walls and rendered absolutely air-tight. With this exception, and though our representative took care to visit some of the poorest neighbourhoods, the pail system seemed to work in a very satisfactory manner. The disposal of the contents of the pail represents a totally different phase of the subject, which must be reserved for another occasion.

(To be continued.)

THE LUNACY COMMISSIONERS' REPORT.

THE Report recently issued by the Commissioners in Lunacy exhibits upon the whole a very satisfactory picture of the national mental health. The annual increase of dementia, which until two years ago was the most persistent and withal the most melancholy feature of the Commissioners' annual record, has at length given place to a movement in the opposite direction, and although the aggregate number of patients under their charge is larger now than at any previous date, yet the increase both in 1885 and 1886 has been less than proportional to the growth of population, so that the percentage has fallen.

"The fact of a proportional decrease," say the Commissioners, "in the figures of last year upon those of its predecessor, which was then a solitary exception, is repeated this year. The rate has now fallen, for lunatics of all classes, to 28·64 per 10,000—a drop of ·34 since 1885. The returns of two years, however, do not afford a sufficient basis upon which to form an opinion as to the causes of this apparently favourable record; and the decline may, indeed, prove by further experience to be rather temporary than permanent."

This cautious statement is abundantly justified by the facts, and, indeed, hardly, as we think, represents their full import. Thus, turning to the table from which the above figures are taken, we observe that the proportions have been worked out not only for the total figures quoted, but also severally for eleven different groups into which they are split up. These groups, with one exception, show the same general characters as the aggregate—that is to say, the past two years have registered a reduction upon the figures to 1885. Even in the exceptional class—that of male pauper lunatics—the percentage at the beginning of 1887 was fractionally less than at the beginning of 1885, although greater than at the beginning of the intermediate year. Thus even the exceptional case falls almost within the rule, and it may fairly be said that the improved mental health of the people at large is a benefit in which all classes share. It will, we think, be evident that a feature which is thus reflected in every section of the analysed figures is much more remarkable than any merely general result, and justifies a more sanguine view respecting the public health than the Commissioners are disposed to put forward.

Turning now to the invalid community, it is obvious to remark that of the 81,000 patients under treatment at the present time, a very preponderating proportion are chronic cases in which any final recovery cannot be expected. But we are glad to notice in the present report indications of increased attention to remedial treatment, and a very gratifying improvement in the number and proportion of recoveries. It is, indeed, true that the very exceptional record of 1885 has caused that of 1886 to show somewhat badly by comparison, but as the eye sweeps the ten years' column given in the report it becomes obvious that in spite of oscillations in both directions a marked upward tendency is observable, and has, upon the whole, been well maintained until the present time. One fact to which it is impossible not to attach the greatest significance in this connexion is thus referred to in the report:—

"In the treatment of the insane, great importance should be attached to the subject of their useful employment. Our aim constantly is to encourage the efforts of superintendents to devise suitable occupations, and to induce their patients to engage in them; and, with the view of ascertaining as nearly as we can the extent to which such efforts have been successful, we have instituted a comparison of the results attained in the years 1877 and 1886 respectively. ..... We find, then, that in 1877 the numbers usefully employed at the time of our visits to all the county and borough asylums bore to the total number of patients the proportion of 56·65 per cent.; while in the year 1886 the proportion was 61·87 per cent. There has thus in ten years been an increase of 5·22 per cent."

The Commissioners add that the superintendents are fully alive to the importance of this subject, and that progressive and substantial improvement may be looked for in this direction. The difficulty, however, of finding suitable occupation, always great, is specially so in the case of the wealthier classes, who furnish patients for the most part to private licensees. Not only have the prejudices of the patients themselves to be studied, but sometimes also the less excusable prejudices of the patients' friends. In this way serious and most unnecessary obstacles are thrown in the path of the medical adviser, and for the present he must circumvent them as best he can. But it may be hoped that the gradual diffusion of information as to the true principles of sound practice in the treatment of the insane will tend to smooth away difficulties of this sort, and to secure for the practitioner in the performance of his arduous task all the assistance that is to be derived from the loyal co-operation and support of his patients' natural guardians.

ETIOLOGY OF SCARLET FEVER.

(Concluded from page 235.)

DR. J. A. RUSSELL, chairman of the Public Health Committee of the Town Council, said that the history of the recent outbreak of scarlatina in Edinburgh pointed to the impossibility of stamping out the disease, or even of limiting such epidemics, under the present conditions, where a stringent law of disease-notification exists in cities and no corresponding safeguard in the rural districts whence they draw their milk supplies. Another source of difficulty is, that it is by no means easy to diagnose slight cases of scarlatina, which are therefore those most likely to pass unobserved and to give rise to milk infection. He was not satisfied that this possible factor had been sufficiently excluded in the Hendon case. In the recent epidemic cause and effect had now been definitely brought to light, though with great difficulty, from the lack of authentic information in regard to cases of disease outside the boundary of the city. The case of the North Merchiston Board School was of great interest in showing the delimitation of infection to the area supplied with contaminated milk. At this school are children from two distinct districts, separated by the Union Canal; and it was striking to note how at the commencement of the epidemic, and for a considerable time after its outbreak, only those from the district with contaminated milk supply were affected, the other district represented at the school remaining entirely free from epidemic scarlatina. In conclusion, he strongly urged the necessity of extending the clauses of the City Police Act which deal with infectious diseases to outlying rural districts.

Dr. J. O. ARTHUR commented on the valuable work done by Drs. Jamieson and Edington, and on the impetus it had

Digitized by Google

given to the close investigation of the cause of the disease. There were certain points on which he disagreed, from personal observation, with the conclusions that might be drawn from their paper. He felt it necessary specially to insist on the fact that the disease is infectious from its very onset; that mouth and throat washes, however constantly applied, cannot prevent the risk of infection with the mucous discharges; that inunction should not be trusted to as a certain method of rendering the desquamation innocuous, and that it is of doubtful advantage, since the continuous application of a germicide substance may interfere with the healthy action of the skin. In regard to milk infection, he held that in typhoid fever it had to be recognised as a proved source of the disease. Not so with any certainty in scarlatina; and in the present instance, though it had been shown how contamination might have taken place, it had not been proved that it had in reality occurred.

Dr. HUNTER, Linlithgow, spoke of the important influence of environment upon the action of the *contagia* of disease, referring to the different effects produced by one virus, in puerperal cases, according as it gains access to the genital tract or to the system in the usual way. In the cervical glandular enlargements, the throat is probably the more satisfactory area to attack with antiseptics, as it is the source of irritation, rather than to apply counter-irritation to the neck, as Dr. Jamieson recommended. In regard to Dr. Jamieson's methods of disinfecting the throat and skin surfaces, he must say it was practically impossible, except in the case of a well-appointed hospital with abundant skilled assistance, and that in the case of children the system was peculiarly difficult.

Dr. ANDREW SMART referred to his reports on the cattle plague, published twenty-one years ago, in which he found a singular resemblance to the descriptions of the Hendon disease as pictured in the reports of Messrs. Power, Cameron, and Klein. He was convinced from this comparison that the Hendon disease was a mild sporadic type of rinderpest; and he further referred to the fact that when his reports were published he stated his opinion that the disease is the bovine analogue of human scarlatina.

The PRESIDENT asked Dr. Smart whether, in the year of the cattle plague, there was any corresponding outbreak of scarlatina among the inhabitants of Edinburgh.

Dr. SMART replied, that though he did not attach any peculiar significance to the fact, there were five times as many cases of scarlatina in Edinburgh during 1866 as in the last twelve months, although the latter period corresponded in part to an epidemic of the disease.

Dr. W. RUSSELL doubted the identity of the diseases in which Dr. Smart's pathological record showed there were certain elements of similarity. Were that identity proved, it would be difficult to explain why in countries where rinderpest is common there are not frequent epidemics of scarlatina.

Dr. JAMES RITCHIE referred to the many points that still needed discussion, and moved the adjournment of the debate, which was agreed to.

The PRESIDENT, in summing up the results of the discussion of the evening, spoke in high praise of the elaborate research conducted by Dr. Edington in Professor Chiene's laboratory. Among other points referred to, he wished especially to direct the earnest attention of the Society to the risks of infection. In bringing forward his plan of prophylaxis, Dr. Jamieson had no intention of abrogating the ordinary and very necessary precautions of isolation, and the disinfection of fomites in the usual way; and it was to be hoped there would be no laxity of view or of practice in this important matter.

The Society then adjourned.

AGRA MEDICAL MISSIONARY INSTITUTION. — The institution at Agra for training natives as medical missionaries has recently been placed in connexion with the Edinburgh Medical Missionary Society. Dr. Valentine is the principal. The students are connected with missions of every Protestant denomination; they attend the course of instruction given in the Government Medical College, and undergo the same examinations as the candidates for Government service. The cost of maintaining a student during the four years of medical study is only £64. The number of students at present is sixteen; but there is accommodation for forty.

THE ALBERT UNIVERSITY OF LONDON.

DRAFT OF CHARTER AS APPROVED BY THE JOINT COMMITTEE OF UNIVERSITY COLLEGE, LONDON, AND KING'S COLLEGE, LONDON, AND ADOPTED BY THE COUNCILS OF UNIVERSITY AND KING'S COLLEGES.

(The insertion of the passages in square brackets [ ] is contingent upon the Royal College of Physicians of London and Royal College of Surgeons of England being associated with the University.)

VICTORIA, by the grace of God, of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith, to all to whom these presents shall come, greeting.

Whereas University College, London, originally incorporated by Royal Charter and reincorporated by Act of Parliament, and King's College, London, also originally incorporated by Royal Charter, and reincorporated by Act of Parliament, lately presented to us in our Council a humble petition under the common seals of these Colleges and thereby represented to us (among other things) as follows:—

That there exists at present in London an urgent demand for the extension of the benefits of university education and for the better encouragement of learning and research, and that it is expedient there should be constituted in and for the London district a University providing for its students the best attainable teaching in all the subjects included in its Faculties, together with the necessary appliances and aids to study, and commending to its students systematic courses of teaching and methods of study, for the efficiency of which it should become responsible; and by the same petition humbly prayed us to be pleased to grant a Charter to a body of persons, to be appointed as therein described to be a University in and for the London district, having power to grant degrees in the Faculties of Arts, Science, and Medicine, with power to add other Faculties; and that we would be pleased to make such orders in the premises as to us in our Royal wisdom and justice might seem meet; now know ye that we, having taken into our Royal consideration the said humble petition, do, by virtue of our prerogative Royal, and of our special grace, certain knowledge and mere motion, by these presents for us, our heirs and successors, will and ordain as follows:—

I. *Foundation of the Albert University of London.*—There shall be and there is hereby constituted and founded a University, in and for London, with the name of the Albert University of London, by which name the Chancellor, and other members of the Albert University of London for the time being shall be, and are hereby, constituted one body corporate, with perpetual succession, and a common seal, and with power, without any further licence in mortmain, to take, purchase, and hold, and also to grant, demise, or otherwise dispose of real and personal property; which University shall have the constitution and powers, and be subject to the regulations, in this our Charter prescribed and contained; and which University is in this our Charter referred to as the University.

II. *Colleges in the University.*—University College, London, and King's College, London, shall be and are hereby constituted Colleges in the University. Other Colleges may from time to time be admitted as Colleges in the University in the manner and subject to the conditions in this our Charter prescribed.

III. [*Association of the Royal College of Physicians of London and the Royal College of Surgeons in England with the University.*—The Royal College of Physicians of London and the Royal College of Surgeons of England shall be associated with the University in the manner in this our Charter prescribed.]

IV. *Medical Schools in the University.*—The Medical Schools of University College, London, and King's College, London, shall be Medical Schools in the University. Every other Medical School in London which is recognised as efficient by any body having power to grant a qualification for registration under the Medical Acts may claim to be admitted as a Medical School in the University in the manner and subject to the conditions in this our Charter prescribed.

V. *University Degrees and Certificates.*—The University shall have power to confer degrees in the Faculties of Arts, Science, and Medicine, and in such other Faculties corresponding to the provinces of study and educational work occupied by the University as shall from time to time be determined by the Council of the University, on all persons, male or female, who shall have pursued a regular course of study in a College or Medical School in the University, and shall submit themselves for examination. Provided that no ordinary medical degree shall be conferred on any person who shall not previously have obtained a qualification for registration under the Medical Acts. The University shall also have power, in the case of students of the University who shall have been resident students of any other University in our dominions, to accept the examinations and periods of residence and study passed by them at such other University as equivalent to such examinations and periods of study in the University as the Council constituted by this our Charter shall from time to time determine. Provided that the Council shall not allow a degree to be conferred on any such student unless such student shall have pursued a course of study in a College or Medical School in the University during such final portion of the period of study as may be determined by the Council and shall have passed the final examination of the University in that course of study. The University shall also have power to admit by special grace graduates of other Universities in our dominions to similar and equal degrees in the University. The University shall also have power to admit to honorary degrees in the University such persons, being at the constitution of the University Fellows of University College, London, Fellows of King's College, London, or past students of the said Colleges, and such other persons as are worthy, in the estimation of the Council, of this distinction. The University shall also have power to grant to students of any College in the University, after such examinations, in such mode and on such conditions as to the University from time to time shall seem fit, certificates of proficiency in any branches of knowledge. The University shall also have power to examine into the efficiency of schools at any academic institutions, and to grant certificates of proficiency to scholars and members thereof. The University may appoint lecturers independently of a College or Medical School to give instruction in any subject, whether it be or be not included in a Faculty.

VI. *Visitor.*—We reserve to ourselves, our heirs, and successors to be the Visitor of the University.

Digitized by Google

VII. *Authorities of the University.*—The authorities of the University shall be the Chancellor of the University, the Vice-Chancellor of the University, the Council, the assemblies of the several Faculties in the University, the Boards of Studies of the several Faculties, and the Convocation of the University.

VIII. *The Chancellor.*—The Chancellor shall be the head of the University, and may preside over meetings of the Council and of Convocation. The Chancellor shall hold office during his life or until his resignation. ———————————— shall be the first Chancellor of the University. In the event of a vacancy occurring in the office of Chancellor within ten years from the date of this our Charter, we reserve to ourselves, our heirs, and successors the right of nominating to the office. Thereafter the Chancellor shall be elected by the Convocation of the University.

IX. *The Vice-Chancellor.*—In the absence of the Chancellor, the Vice-Chancellor of the University shall exercise all the functions of the Chancellor, except the hearing of appeals under any provision of this our Charter. The first Vice-Chancellor shall be appointed by the Chancellor from among the members of the Council, and shall hold office for two years from the date of election, or until he shall cease to be a member of the Council, whichever shall first happen. His successors shall from time to time be elected by the Council from among the members of the Council, and shall hold office for one year. The Vice-Chancellor may appoint a member of the Council as a pro-Vice-Chancellor to exercise his functions in his absence.

X. *The Council.*—The Council shall consist of the persons following—namely: first, the Chancellor; secondly, persons appointed by this our Charter, and their successors appointed by the Lord President of our Council, and by the Convocation of the University, as in this our Charter provided; thirdly, persons representing the several Colleges in the University; fourthly [persons representing the Royal College of Physicians of London and the Royal College of Surgeons of England fifthly], persons representing the several assemblies of the Faculties in the University. Except as in this our Charter provided, every member of the Council shall hold office for the term of five years, and shall be capable of reappointment or re-election. Any member who shall cease to be qualified, or shall become incapacitated to act, or shall notify his resignation to the Council, or shall for the space of two years consecutively be absent from all meetings of the Council, shall thereupon cease to be a member of the Council. The following six persons shall be members of the Council from the the date of this our Charter:——— On any such person or successor of such person ceasing to be a member of the Council, the Lord President of our Council shall appoint a fit person as his successor, provided that after the expiration of ten years from the date of this our Charter, the Convocation of the University shall elect a fit person to succeed to the first, the third, and the fifth vacancy so caused, and on any person so elected, or a successor of such person ceasing to be a member of the Council, shall elect a fit person to be his successor. The persons in the Council representing University College, London, shall be three persons chosen by the Council of the College. The persons in the Council representing King's College, London, shall be three persons chosen by the Council of the College. On the admission of any College other than University College, London, and King's College, London, as a College in the University, the number of its representatives, not exceeding three, shall be determined by the Council. [The persons in the Council representing the Royal College of Physicians of London shall be three persons chosen by the Fellows in Comitia of the College. The persons in the Council representing the Royal College of Surgeons of England shall be three persons chosen by the Council of the College.] The persons representing each of the assemblies of the Faculties of Arts, Science, and Medicine shall be four persons appointed by the assemblies of such Faculties respectively. If any other Faculty shall be established by the University, the persons representing such Faculty in the Council shall be such number of persons to be elected by the assembly of such Faculty not exceeding four as shall on the establishment of the Faculty be determined by the Council. Any College represented on the Council, or any assembly of a Faculty may, at any time after six years from the constitution of the University, present a memorial to the Council requiring its number of representatives, or the number of representatives of any other College or assembly of a Faculty, to be taken into consideration, with a view to its increase or decrease, and the Council shall thereupon refer the matter to the several Colleges and assemblies of the Faculties other than that presenting the memorial, and after receipt and consideration of such of the reports as may be received within three months from the date of reference, the Council may increase or decrease the number of representatives to which such memorial relates. Provided that within six months after the promulgation of the decision of the Council any College or assembly of a Faculty may appeal to us in our Council against the decision of the Council of the University. The acts of the Council shall not be invalidated by the existence of any vacancy among its members.

XI. *Powers of the Council.*—The Council shall be the governing body of the University, and shall direct the form, custody, and use of the common seal, and shall have the management and control of the affairs and property of the University, and shall appoint a registrar and any other officers necessary for conducting the business of the University. The Council shall have full power to make and alter or revoke statutes for regulating all matters concerning the University, and may exercise and do all powers and things by this our Charter granted or authorised to be exercised or done by the University. Provided, first, that it shall not be lawful for the University, by any statute or otherwise, to adopt or impose on any person any test whatsoever of religious belief or profession; and provided, secondly, that any statute made by the Council be not repugnant to the law of England, or to the general objects, or any provision, of this our Charter. Provided, thirdly, that the Council, in determining the curriculum of each Faculty, and making regulations respecting the examinations or degrees of the Faculty shall proceed on the recommendation of, or after submitting the proposal for consideration and report to, the assembly of the Faculty.

XII. *The Assemblies of the Faculties.*—The assemblies of each of the Faculties of Arts and Science, and of any other Faculty that may hereafter be established by the University, shall consist, in the first place, of such persons doing professorial work in the Colleges included in the University in respect of that Faculty, as shall be designated by the governing body of each College, and for this purpose University College, London, and King's College, London, shall, at the constitution of the University, be deemed to be included therein in respect of the Faculties of Arts and Science. The assembly of the Faculty of Medicine shall consist, in the first place, of such persons doing professorial work in the Colleges and Medical Schools in the University as shall be designated by the governing body of each College or Medical School. The persons whom a College or Medical School shall be entitled to designate as members of the assembly of a Faculty shall be such as are giving regular instruction to classes in the College or Medical School in one or more of the subjects included in the Faculty. Provided that, except in the case of the persons designated as aforesaid before the first election of the Council by the assemblies of the Faculties, the designations of persons to be members of the assemblies of the Faculties shall not take effect without the approval of the Council, or on appeal to the Chancellor, his approval of the same. The assembly of each Faculty shall consist, in the second place, of such of the examiners of the University in subjects included in the Faculty, not being otherwise members of the assembly, as the Council may appoint members of the assembly; provided that such examiners shall not vote in the assembly of the Faculty on the election of members of the Council. It may consist, in the third place, of such persons engaged, or who have been engaged, in University teaching in London in subjects included in the Faculty as shall be nominated in that behalf by the assembly of the Faculty and approved by the Council.

XIII. *Powers of the Assemblies of the Faculties.*—The assembly of each Faculty shall have the following powers—namely: Of prescribing the mode of conducting the proceedings of the assembly and of registering the same, and of reporting the same to the Council; of electing members of the Council, and of the Board or Boards of Studies of the Faculty; of discussing and of declaring an opinion on any matter whatsoever relating to the University, including any matter referred to the assembly by the Council; of delegating from time to time to the Board or Boards of Studies of the Faculty the power of making recommendations and reports to the Council.

XIV. *Establishment of New Faculties.*—Before establishing any new Faculty the Council shall refer the matter to the assemblies of the Faculties for consideration and report. When a new Faculty has been established, the Council shall determine which of the Colleges in the University shall be deemed to be included in the University in respect of such Faculty.

XV. *The Boards of Studies.*—There shall be a Board or Boards of Studies in each Faculty, which shall consist of, first, members of the Faculty elected from time to time by the assembly of the Faculty from amongst its own members; secondly, such of the examiners of the University in the subjects of the Faculty as are members of the assembly of that Faculty. The Council shall have power to refer matters to the Boards of Studies, either separately or conjointly, for consideration and report; provided that a copy of each such report shall be transmitted forthwith to the assembly of each Faculty concerned. The Boards of Studies shall have power to meet with each other in conference, either by themselves or by their committees, to prescribe the mode of conducting their own proceedings, and to report directly to the Council, either separately or conjointly, on any matter relating to the subjects of their Faculty or Faculties.

XVI. *The Convocation of the University.*—The Convocation of the University shall consist of the Chancellor, Vice-Chancellor, and registered graduates of the University for the time being. All graduates of the University of three years' standing shall be entitled to register, and for this purpose a Register shall be kept, which shall be conclusive evidence that any person whose name appears thereon at the time of claiming to vote in Convocation is entitled to vote, and that any person whose name does not then appear thereon is not so entitled; provided that the holder of an *ad eundem* or honorary degree shall not, as such, without the consent of Convocation in each case, be entitled so to register. The first meeting of Convocation shall be called by the Vice-Chancellor, at the expiration of ten years after the date of this our Charter. At that meeting the Convocation shall elect a chairman, who shall hold office for three years, or until his previous death or resignation, but a chairman going out of office shall be re-eligible. The Council shall, as often as may be required for the election of members of Council, and may at such other times as to them seems fit, convene a meeting of Convocation. If at any time twenty members of Convocation, by writing under their hands, require the chairman to convene a meeting of Convocation, he may in his discretion do so. Notice of all meetings of Convocation shall be given in such manner as the Council shall prescribe. No question shall be decided at a meeting of Convocation unless at least thirty members are present, but in the election of members of the Council, members of Convocation shall be entitled to vote by voting papers in such form, and to be signed, verified, and transmitted in such manner as the Council shall prescribe.

XVII. *Powers of Convocation.*—The Convocation shall have the following powers—namely: Of prescribing the mode of conducting the proceedings of the Convocation and of registering the same, and of reporting the same to the Council; of electing the Chancellor of the University after the first vacancy in the office which shall occur subsequently to the expiration of ten years from the date of this our Charter; of electing members of the Council as aforesaid; of discussing and of declaring an opinion on any matter whatsoever relating to the University, including any matter referred to them by the Council.

XVIII. *Members of the University.*—The members of the University shall be the Chancellor, the Vice-Chancellor, the members of the Council; the members of the assemblies of the Faculties; the registrar, graduates, and students of the University. The students of the University shall be such students in any College or Medical School in the University as shall have been admitted as students of the University under the regulations of the Council.

XIX. *Examinations.*—The examiners of the University shall be such members of the assemblies of the Faculties, and such external examiners, as the Council shall from time to time appoint to be examiners. All examinations of members of the University shall be conducted jointly by external examiners and by examiners being professors, physicians, surgeons, lecturers, or teachers in a College or Medical School in the University; and for this purpose at least one external examiner shall be appointed by the Council for each subject forming part of the course of study required for a degree. For each examination the Council shall form a board, or boards, consisting of all or some of the examiners, to which the examination papers shall be submitted previously to the examination.

XX. *Place for Meetings.*—Unless and until the University shall possess other buildings proper in this behalf, all meetings directed to be held

Digitized by Google

under this our Charter shall be held, and all degrees granted and examinations for degrees held by the University shall be granted and held in buildings provided by the Colleges of the University or otherwise with the approval of the Council. Nothing in this our Charter shall prevent the University from conferring any degree by special grace on any qualified person in his absence.

XXI. *Property.*—Notwithstanding anything in this our Charter, the University shall not at any time hold real property in our United Kingdom exceeding the annual value of ten thousand pounds (according to the value of such property at the time of its acquisition) over and above the value of the site, buildings, and hereditaments of the University used and occupied for the immediate purposes thereof.

XXII. *Fees.*—The University may demand and receive for degrees and other distinctions, and for certificates of proficiency and other certificates, and on examinations conducted by the University, such fees as the Council shall from time to time appoint; and the produce of all such fees shall be applied in or towards discharge of the expenses of the execution of this our Charter. Every member of Convocation shall pay such fees, at such times, and with such liberty to compound for the same, as the Council shall from time to time direct, and on default may be removed from the Register.

XXIII. *Contributions of Colleges and Medical Schools.*—In case the produce of such fees is insufficient to meet the ordinary expenses of the management of the University, together with the expenses of conducting examinations and conferring degrees, the Council may require from the several Colleges and Medical Schools in the University contributions for defraying those expenses; and in fixing the amount thereof the Council shall consider a report to be made in each case by a committee, consisting of seven members of the Council, of whom three at least shall be of the six members appointed by this our Charter, or their successors; which committee in making their report shall have regard to the relative magnitude and resources of the several Colleges. Any College or Medical School may, within two calendar months after the receipt of any such requisition from the Council, appeal against it to the Chancellor of the University, whose decision shall be final.

XXIV. *Fellowships and other Emoluments.*—The University from time to time may found and endow fellowships, scholarships, exhibitions, and other prizes, for which funds may by devise, bequest, donation, grant, or otherwise be supplied, and may make regulations respecting the same, and the tenure thereof, but not so as in any way to interfere with the regulations respecting the entrance or admission of students to any College or Medical School in the University.

XXV. *Admission of Colleges and Medical Schools.*—The Council, after considering in each case a report to be made by the assembly or assemblies of the Faculty or Faculties in respect of which the application is made, may accept the application of any College in the London district to be admitted as a College in the University on the Council being satisfied—first, that the College is established on a basis justifying the expectation of its permanent existence, and is under the independent control of its own governing body; secondly, that the College possesses a sufficient staff, buildings, and appliances, with adequate arrangements for teaching and study, in the Faculty or Faculties in respect of which the application is granted. A Medical School admitted to the University shall be admitted in respect of the Faculty of Medicine. If any Medical School shall apply to be admitted to the University in respect of any Faculty other than the Faculty of Medicine, the claim shall be considered and decided in the same manner, and subject to the same conditions as in the case of a College claiming to be admitted to the University, except only as regards the condition that it is under the independent control of its own governing body. In case the Council refuse any such application, the College or Medical School applying may appeal to us in our Council against such refusal. The governing body of a Medical School admitted to the University in respect of any Faculty other than the Faculty of Medicine shall be entitled to designate professors and lecturers of the School to be members of the assembly of the Faculty, subject nevertheless to the same conditions and provisions as are hereinbefore contained with regard to the persons whom a College shall be entitled to designate as members of the assembly of a Faculty, and with regard to the approval required before such designations take effect.

XXVI. *Authority over Colleges.*—A College or Medical School in the University shall not in any way be under the jurisdiction or control of the Council, except as regards the regulations for the duration and nature of the studies to be required of the students of the College or School as a qualification for University degrees or distinctions.

XXVII. *Exclusion of Colleges.*—The Council may, from time to time, revise the list of Colleges and Medical Schools in the University, and on its appearing that any College or Medical School has ceased to possess the qualifications for admission in this our Charter prescribed, or is in other respects no longer efficient, the Council, after considering a report to be made in each case by the assembly or assemblies of the Faculty or Faculties in respect of which the College or Medical School has been included in the University, may exclude that College or Medical School from the University. On such exclusion members of the Council representing or elected by that College shall cease to be such; and the professors and teachers of that College or Medical School shall cease to be by virtue of their office members of the assembly of any Faculty of the University, or examiners of the University; but the students of the University, then members of that College or Medical School, shall, if the requisite instruction is given therein, be allowed by the University to complete in that College or Medical School the courses of study necessary for the attainment of the degrees of the University. No member of a College or Medical School excluded shall, on account of such exclusion, be deprived of any right, privilege, or emolument possessed by him by virtue of any degree, reward, or distinction granted to or conferred on him by the University. Provided that not less than one year before a proposal to exclude a College or Medical School from the University is considered by the Council notice in writing of such proposal shall be given to the College or Medical School; and no such exclusion shall take effect until the expiration of six calendar months from the date of the decision of the Council; and within those six months the College or Medical School may appeal to us in our Council against such exclusion.

XXVIII. *Definition of London District.*—The London district for the purposes of the University shall mean a radius of fifteen miles from Somerset House.

In witness, &c.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Chelsea.—Dr. Seaton in his annual report for 1886 discusses the question of the means of spread and prevention of the principal infectious diseases that have prevailed, and he refers especially to the high mortality from diphtheria. He believes that defective house-drainage has little or nothing to do with this disease. Unquestionably, infection in schools and elsewhere plays a wide part in the spread of diphtheria, but there can be little doubt that people having congested and inflamed fauces do suffer from a disease akin to diphtheria when their throats are exposed, by inhalation, to emanations of sewer air. Without ignoring what Dr. Seaton so strongly presses—namely, the infectious character of the disease,—we think no one would be justified in setting aside the possible influence, as regards the spread of the malady, of defective conditions of sewerage and house-drainage. The current sanitary work of the year has consisted in such matters as the systematic removal of nuisances, the inspection of lodging-houses, disinfection, and inspections and analysis of foods, drugs, and medicine. In one instance a case of typhus occurred in connexion with conditions of overcrowding. The death-rate for the year was 20·4 and the birth-rate 33·1 per 1000 of the inhabitants.

Wandsworth.—This district is cut up into six portions for medical officer of health purposes. On the whole area the birth-rate was 34·5 and the death-rate 17·1 per 1000. The deaths under one year of age to every 1000 births were 164, as opposed to 150 in England and Wales as a whole, and to 169 in the great towns. Amongst the cases of infectious disease isolated in the Metropolitan Asylums Board hospitals were 4 from small-pox, 76 from scarlet fever, and 34 from enteric fever. Following upon the general review of the whole distict, each officer contributes a local summary. Dr. Kempster, referring to the past need for additional sewer ventilation by means other than street surface ventilators, expresses approval of the up-cast shafts, which have effected much improvement; Dr. Oakman, in giving details as to sanitary work, refers to the fact that to 405 closets water has been laid on, an improvement of the first importance in an urban district; Dr. Newsholme, dealing with the question of dust-destructors, explains the precautions to be taken as regards the one for Clapham, and expresses the opinion that the results of its working will be altogether satisfactory if carried out on the lines indicated. In the other sub-districts detailed accounts of work effected are given.

Leicester Urban District.—The death-rate for this borough during 1886 was 19·6 per 1000, which compares favourably with the average of 21·2 during the past ten years; and, apart from measles, there was no serious outbreak. As to notification of infectious diseases, Dr. Tomkins's opinion is to the effect that as regards erysipelas such notification is for sanitary purposes of very slight service, and that the money spent on it is little better than wasted. The bulk of the cases are of a trivial character, and he advocates their removal from the list. The general antagonism to the system as a whole has steadily disappeared in Leicester, and some of its most prominent medical opponents are now amongst its warmest advocates. The knowledge gained of infectious disease generally has turned out to be of the utmost value, and the view is expressed that the system should be applied to the population as a whole. Compared with 1885, which was by no means an unfavourable year, the following diseases show substantial reductions in mortality: scarlet fever, a decrease of 30 per cent.; measles, 25; diphtheria, 60; whooping-cough, 50; and typhoid fever, 50; but diarrhœa stands out once more as a blot upon an otherwise fair record, 256 deaths having been occasioned by it against 186 during the preceding year. The mean temperature during the third quarter was in excess of the mean for the past 115 years, and the rainfall was 2·46 inches below the average for the past seventy years. Norwich alone, lying as it does in a hollow, with a damp subsoil in the lower parts of the town, exceeded in its diarrhœa mortality that of Leicester. The subject of the etiology of the disease has engaged much

Digitized by Google

of Dr. Tomkins's attention, and he is known to be aiding Dr. Ballard in his extended investigation into the subject. Summing up some of his own views, Dr. Tomkins reports that in the "diarrhœa area" of the town the micro-organisms or their germs exist in tenfold abundance compared with other parts; that from the bodies and organs of patients dead of diarrhœa micro-organisms have been obtained; and that cultivated specimens when taken into the body are capable of producing diarrhœa. It is not, however, stated that the diarrhœa organism has been isolated. In so far as general causes are concerned, warmth, moisture, and dead organic matter, with the absence of light and air, are potent factors in the production of the disease. The general body of the report indicates steady progress, and contains advice as to future action for the improvement of health in the borough.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5766 births and 4115 deaths were registered during the week ending July 30th. The annual rate of mortality in these towns, which had increased in the preceding five weeks from 17·6 to 22·2 per 1000, further rose last week to 23·2. During the first four weeks of the current quarter the death-rate in these towns averaged 21·4 per 1000, and was 0·5 above the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 12·7 in Huddersfield, 13·9 in Derby, 14·1 in Brighton, and 14·5 in Sunderland. The rates in the other towns ranged upwards to 27·2 in Birkenhead, 27·7 in Plymouth and in Leeds, and 30·1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the preceding four weeks from 486 to 1173, further rose last week to 1301, owing to the continued increase of the mortality from diarrhœa; they included 921 from diarrhœa, 163 from whooping-cough, 121 from measles, 46 from scarlet fever, 25 from diphtheria, 24 from "fever" (principally enteric), and only one from small-pox. These zymotic diseases caused the lowest death-rates last week in Plymouth and Cardiff, and the highest in Birkenhead, Leeds, and Leicester. Diarrhœa caused the greatest mortality in London, Leeds, Preston, and Leicester; whooping-cough in London, Norwich, and Birmingham; measles in Manchester, Salford, and Birkenhead; and scarlet fever in Blackburn and Bristol. Of the 25 deaths from diphtheria in the twenty-eight towns, 20 occurred in London. Small-pox caused 1 death in Sheffield, but not one in Greater London, or in any of the twenty-six other large provincial towns. Only one case of small-pox was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The mortality from diarrhœa did not considerably exceed the average for the season. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding four weeks from 199 to 174, further fell last week to 160, and were 30 below the corrected average. The causes of 87, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Brighton, Bolton, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Sheffield, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·8, 19·5, and 20·9 per 1000 in the preceding three weeks, declined again to 19·9 in the week ending July 30th; this rate was 3·3 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 6·5 and 18·3 in Perth and Glasgow, to 22·7 in Dundee and 28·1 in Leith. The 497 deaths in the eight towns last week showed a decline of 26 from the number in the previous week, and included 41 which were referred to whooping-cough, 39 to diarrhœa, 12 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 4 to measles, 3 to diphtheria, and not one to small-pox; in all, 103 deaths resulted from these principal zymotic diseases, against 84, 93, and 103 in the preceding three weeks. These 103 deaths were equal to an annual rate of 4·1 per 1000, which was 3·2 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 46, 43, and 37 in the preceding three weeks, rose again last week to 41, and included 11 in Glasgow, 9 in Edinburgh, 9 in Dundee, and 6 in Greenock. The 39 deaths attributed to diarrhœal diseases corresponded with the number in the previous week, but were 5 above the number in the corresponding week of last year; they included 15 in Glasgow, 7 in Edinburgh, 6 in Dundee, 5 in Paisley, and 4 in Leith. The fatal cases of scarlet fever, which had been 11 and 5 in the previous two weeks, rose last week to 12, of which 9 were returned in Glasgow and 3 in Dundee. Two of the 4 deaths from "fever," 3 of the 4 from measles, and 2 of the 3 from diphtheria occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 65 and 77, in the previous two weeks, declined again last week to 62, and were one below the number returned in the corresponding week of last year. The causes of 48, or more than 9 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 26·6, 27·9, and 29·9 per 1000 in the preceding three weeks, further rose to 30·9 in the week ending July 30th. During the first four weeks of the current quarter the death-rate in the city averaged 28·8 per 1000, the mean rate during the same period being but 22·8 in London and 19·4 in Edinburgh. The 209 deaths in Dublin last week showed a further increase of 7 upon the numbers returned in the preceding three weeks; they included 22 which were referred to measles, 16 to diarrhœa, 3 to "fever" (typhus, enteric, or simple), 3 to diphtheria, 3 to whooping-cough, 2 to scarlet fever, and not one to small-pox. Thus the deaths resulting from these principal zymotic diseases, which had increased in the eight previous weeks from 21 to 48, further rose last week to 49, and exceeded the number in any previous week of this year; they were equal to an annual rate of 7·2 per 1000, the rates from the same diseases being 3·9 in London and 3·4 in Edinburgh. The fatal cases of measles, which had been 36, 28, and 21 in the preceding three weeks, were last week 22. The deaths attributed to diarrhœa, however, declined from 21 to 16. The three deaths referred to diphtheria exceeded the number registered in any previous week of this year; while the fatal cases of the other zymotic diseases all but corresponded with recent weekly numbers. The deaths of infants showed a further considerable increase, whereas those of elderly persons were fewer than in any recent week. Five inquest cases and 5 deaths from violence were registered; and 68, or very nearly a third, of the deaths occurred in public institutions. The causes of 24, or nearly 12 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Deputy Surgeon-General Duncan Alexander Campbell Fraser, M.D., to be Surgeon-General, vice J. Hendley, C.B., retired (dated June 21st, 1887); Brigade Surgeon Robert Walter Clifton, to be Deputy Surgeon-General, vice D. A. C. Fraser, M.D. (dated June 21st, 1887); Surgeon-Major Alexander Ferrier Churchhill, M.B., to be Brigade Surgeon, vice R. W. Clifton (dated June 21st, 1887). The undermentioned Surgeons-Major are granted retired pay with the honorary rank of Brigade Surgeon:—Thomas Campbell Tolmie and Charles Frederick Richards, M.B. (dated August 3rd, 1887).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Surgeon George William Frederick Armstrong, M.D., has been placed on the retired list of his rank (dated June 25th, 1887).

The following appointments have been made:—Surgeon Christopher Pearson, to the *Gannet:* Surgeon Charles W. Hamilton, to the Royal Marine Division at Eastney; Surgeon George L. Baker, to the *Excellent:* and Mr. Joseph H. Wallis to be Surgeon and Agent at St. Thomas and St. Anthony.

ROYAL NAVAL ARTILLERY VOLUNTEERS (Liverpool Brigade).—Griffith Richard Griffith, M.B., to be Surgeon (dated July 29th, 1887).

Digitized by Google

THE HONORABLE ARTILLERY COMPANY OF LONDON.—The commission of the following officer is renewed for five years from July 14th, 1887:—Surgeon William Peter Rawlins.

ARTILLERY VOLUNTEERS.—2nd Lancashire: Surgeon J. C. Cormack resigns his commission (dated July 30th, 1887).—1st East Riding of Yorkshire: Acting Surgeon E. Clarkson resigns his appointment (dated July 30th, 1887).

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Sherwood Foresters (Derbyshire Regiment): Surgeon A. H. Dolman resigns his commission; also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the Battalion on his retirement (dated July 30th, 1887).—1st Volunteer Battalion, the King's Own (Royal Lancaster Regiment): Surgeon and Honorary Surgeon-Major J. Robinson resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated July 30th, 1887).—2nd London: Acting Surgeon F. E. Fenton resigns his appointment (dated July 30th, 1887); Adam Robert Hamilton Oakley, Gent., to be Acting Surgeon (dated July 30th, 1887).—4th Volunteer Battalion, the South Wales Borderers: Acting Surgeon S. B. Mason to be Surgeon (dated July 30th, 1887).—4th Volunteer Battalion, the Norfolk Regiment:—Acting Surgeon E. T. Prior to be Surgeon (dated July 30th, 1887).

Correspondence.

"Audi alteram partem."

"DISEASE AND MEDICAL ATTENDANCE AT WORKHOUSES."

To the Editors of THE LANCET.

SIRS,—In your issue of the 23rd ult. you devote a leading article to the subject of an inquest at St. George's-in-the-East Workhouse on the body of a woman aged eighty-seven years. I have not seen a detailed account of the inquest, and I take your statement to be perfectly correct. As, however, some of your inferences are calculated to mislead not only the profession, but the general public, I shall, I hope, be pardoned if I point out one, at least, of the errors into which you have fallen, through, I am sure, an earnest endeavour to advance not only the public interest, but that of the profession generally.

In your article you lay stress upon the question of admitting a "second medical opinion" into the workhouse, and suggest that such should be provided at the expense either of the ratepayers or of the relatives of the inmate. A second opinion *is* provided by the guardians to all, or nearly all, of the metropolitan workhouses, and to the one in question, in the form of an assistant medical officer; and the medical officers, in my experience, are generally ready to accept any suggestions offered by their assistants, whilst the assistants, on the other hand, are obliged to seek the advice of the medical officer when any doubt arises as to the treatment of any inmate. If the near relatives (in this instance a nephew) of the inmate are anxious about his condition, and at the same time are in a position to pay a practitioner, not a medical officer of the workhouse, a consulting fee, I hope I shall be forgiven if I suggest that it is not creditable to them that the person in question should ever have been admitted into the workhouse, and thus cast as a burden upon the already heavily pressed ratepayer.

With reference to the admission of an outside second opinion at the request of the friends, I think that, on carefully considering the question, you will see the utter impracticability of such a system, and I venture to say that there is not even a medical guardian in London who would make himself responsible for such a proposal. Must the poorer and more struggling ratepayers be still further oppressed by being compelled to pay for affording "pleasure" to the relatives of aged inmates of workhouses which are already provided with *two* doubly qualified medical practitioners?—ratepayers whom I know in many instances are unable to pay for ordinary qualified advice, and are obliged to seek the advice of the host of unqualified "doctors" which infest this union and advertise medicine and advice for fourpence. To them, indeed, "the limitations of art are becoming painfully apparent." In a large proportion of cases, if external medical advice were admitted into the workhouse *at the dictation of friends*, the persons whom we should be asked to consult with would be the unqualified practitioners of whom I have spoken. Both the medical officer and the assistant medical officer are obliged to be doubly qualified practitioners; but the advice with which many of the poorer ratepayers are obliged to be content is often unqualified, or confined to one qualification of an inferior order.

If, therefore, you can use your great influence in elevating the tone of the class of practitioners who are employed both by the poorer ratepayers and those people bordering upon pauperism, you will not only greatly benefit the people at large, but you will thus make your suggestion a little more practicable, although its adoption would still destroy the individual responsibility so necessary in the management of large public institutions.

With reference to the question of the medical officer not having been summoned, that is evidently a negligence on the part of the night nurse, the following being in this union the rule set for her guidance: "In all cases of doubt or emergency to summon the medical officer." There is at the present time an honest endeavour being made, both by guardians and medical officers, to improve not only the nursing, but the medical attendance in workhouses and infirmaries. In some places qualified clinical assistants have been appointed to assist the staff, and in others the appointment of consulting physicians and surgeons is under consideration; whilst in nearly all unions the guardians place no restrictions on the medical officer sending to special or general hospitals cases which, in his opinion, would be benefited by special treatment and maintaining them there.

I am, Sirs, your obedient servant,

HENRY J. DIXON.
Assistant Medical Officer of the Infirmary and Workhouse of the Greenwich Union.

August, 1887.

THE SEWAGE OF LONDON.

To the Editors of THE LANCET.

SIRS,—There is a grave question of public health now in imminent danger of being dealt with in a manner which may, and probably will, result in the production and perpetuation for some time of a serious nuisance. It is reported that the Metropolitan Board of Works, by a small majority, being in fact a minority of the Board, have reversed the policy hitherto followed, and for the last two years with complete success, with regard to the deodorisation of the London sewage, and have sanctioned the revival of processes which abundant and costly experience has shown to be unavailing and productive of evil. Under these circumstances the attention of all sanitarians must be earnestly directed to the subject, and I implore your powerful aid in laying the matter before the profession as the natural guardian of public health.

It will be remembered by your readers that the river Thames was in the year 1884 in a deplorable state, and that, after much agitation and strong expressions of opinion on the part of a Royal Commission and of the Home Secretary, the Board at last adopted measures to abate the nuisance which undoubtedly existed. Some thousands of barrels of chloride of lime, or so-called bleach, were thrown at intervals into the outflowing sewage. The effect was that while the specific odour of the sewage exhaled by the Thames at the outfalls at Barking and Crossness, and for some miles up and down the river, was no doubt destroyed, another complication of nuisances was developed, emanating more particularly from the mud-banks at low water and from deposits roused by the shipping, and exceeding in intensity those previously existing. When this unforeseen result had been recognised, the Board, mindful of its high duty, commenced in the autumn of 1884 to use manganate of soda for the deodorisation of the effluent sewage. As only small parcels of this deodorant could be bought in trade, and these at a very high price, the Board during the winter of 1884-85 erected special works for its production, and manufactured such a supply that during the summer of 1885, bleach having been almost entirely abandoned, and the trade supply of manganate having been increased and greatly

Digitized by Google

cheapened, deodorisation was carried out by manganate and sulphuric acid. This was effected at the outflow stations, Barking and Crossness, as well as at various stations within the metropolis, upon the flowing contents of the sewers. The results were so satisfactory that there were no reasonable complaints as regards either the sewers or the river during the entire season. In 1886 more manganate was used, and at a greater number of stations than in the previous year, and had again the desired effect, so that the Thames remained in an unexceptionable condition. As the processes appeared expensive, the Board obtained the opinion of a committee of chemists, consisting of Sir F. Abel, and Professors Odling, Williamson, and Dupré, who entirely approved of all that had been done, and, if I am correctly informed, particularly of the use of manganate and sulphuric acid as opposed to chloride of lime. In the meantime the Board proceeded to complete its contemplated arrangements for the purification of the sewage by precipitation. The works necessary for the treatment of the sewage at Barking were given into the hands of a contractor; the plans for those required at Crossness were prepared by the engineers. An experimental steamer, intended for the removal of the sludge to the sea, was constructed, and is now lying ready for service at Erith. Nevertheless, two years will probably elapse before the whole of the contemplated works can be completed, and the precipitation of the whole of the sewage by lime and protosulphate of iron, and the deodorisation of the effluent by manganate, can be carried out. The Board has from time to time given permission to enterprising individuals, amongst whom there were even foreigners, to practically try their particular schemes with the aid, and even at the expense of the Board. Nobody would object to such generosity, as it would afford the best means for all that is good to assert itself, and for useless propositions to show their futility. I believe that the Board literally derived no information whatever from its liberality. The river Thames, as far as it is affected by the London sewage, is already in a state causing considerable apprehension to those who may be considered to be responsible for it; owing to the effects of a very dry season, it will probably be as bad as, if not worse than, it was in 1884. Then the evil odour was never entirely subdued, but only changed, and as some say, aggravated. If the precedents of 1885 and 1886 be not at once followed, and deodorisation with manganate and sulphuric acid be carried out both at the outfalls and at numerous stations within the metropolis, the consequences will be the production of a great nuisance, highly disagreeable, and not without danger to health and life. It is said that the Board, under the advice of Sir Henry Roscoe, M.P., and in opposition to the experience of the last two years, and setting aside the advice of the committee of chemists above mentioned, and their own officers, are going to resume the application of chloride of lime to the unprecipitated sewage discharged into the river, and discontinue altogether the use of manganate at the outfalls as well as at the metropolitan stations on the sewers. This will probably appear to all persons who have followed the progress of the subject from the chemical, medical, and public health standpoint, to be a retrograde movement. For not only has the use of bleach been condemned by the clearest experience, as engendering a nuisance of a new and peculiar kind on all the mud-banks within reach of the sewage, but the mere manipulation of the chloride of lime by workmen in confined spaces during the three hours of sewage discharge is so detrimental to the health of the labourers that it ought never to be imposed upon them. Manganate and sulphuric acid, on the other hand, have no smell, their action never results in the production of smelling products, and they do not destroy those minute vegetable and animal organisms which are essential for the rapid purification of water from admixed sewage matters. By bleach or chloride of lime, on the other hand, they are mostly destroyed, and this is the main reason for the prevalence of foul smells following the use of bleach.

[illegible] ayers, sanitarians, and inhabitants of the border [illegible] Thames below Greenwich should therefore join in [illegible] against this intended retrograde movement, and [illegible] respectfully and firmly urge upon the Metropolitan [illegible] Works the immediate resumption of the processes [illegible] which the experience of two years has [illegible] to be efficient and protective to the public.

I am, Sirs, your obedient servant,

[illegible] Park, Vic. SANITARIAN.

"A DOCTOR'S INCOME."

To the Editors of THE LANCET.

SIRS,—If you do not consider the subject closed, will you allow me the privilege of the opener of a debate—the right of reply? I notice that you, in your article on the subject (for which, by the way, the profession owe you a debt), and all those who have joined in the discussion, are agreed that matters are as I have stated. But when it comes to discussing remedies, it is another matter. You have scarcely referred to those I have suggested. No one has expressed any warmth in favour of my proposals. No one has made any feasible alternative proposal. This is sad, as it seems to imply that poverty is our certain and unavoidable lot for many a long year, and no remedy is available. I may mention that I expressly excluded *London* hospitals from my consideration; so that a London hospital physician's criticism is beside the mark. I have myself practised as a London consulting physician, and acknowledge the truth of the picture he drew; but it was the county hospitals I referred to as ruining the general practitioner. I have received many letters on the subject, and one conclusion seems inevitable—there is one class of practitioners, and only one, which is doing fairly well, and that is the class that has inherited the trade instincts of our predecessors the apothecaries. A chemist once said to me that he never knew a "college gentleman" who did well in private practice, and he had come to the conclusion that college life spoiled a man for *business*. What he meant is exemplified by the following extract from the ledger of a medical man who understood *business* in the same sense that the chemist did: "Consultation fee, 5*s*.; bottle of mixture, 3*s*. 6*d*.; two pills, 2*s*. 6*d*.; application for throat, 2*s*. 6*d*.; brush for applying ditto, 1*s*.; total, 14*s*. 6*d*." I ought to state that the patient was a very rich man, and well able to pay a good fee; but is there no hope for a medical man unless he is business-like enough to sell a penny camel's hair brush for a shilling? I am, Sirs, yours obediently,

Southborough, Tunbridge Wells. E. PAGET THURSTAN, M.D.

TRACHEOTOMY AND INFLATION IN THE TREATMENT OF A STILLBORN CHILD.

To the Editors of THE LANCET.

SIRS,—Permit me to reply to Mr. Jennings' letter in your issue of July 23rd, which I have only just seen. It seems to me that the explanation there given of stillbirth—that it is due to a valve-like action of the epiglottis preventing inspiration—is a little too simple. I know that it was not so in my case, for this reason: during the time I was trying to pass a catheter into the larynx by the mouth, I held the epiglottis and tongue forward with my finger, effectually preventing any valve-like action, but no air entered the lungs on attempted inspiration. I think that the presence of mucus and meconium in the trachea, and probably also in the larynx, was at least the chief cause of the inability to inspire. Moreover, after tracheotomy, the child not only breathed but was aided in doing so by inflation, yet the resulting expansion of lung was not enough to maintain life. Is it likely that if the larynx could have been cleared by any manœuvre, and inflation replaced by artificial respiration, the expansion would have been greater? Artificial respiration has always seemed to me a very feeble proceeding in a stillborn child with flaccid muscles and yielding chest walls. What I meant to suggest was that such stillborn children—and *a fortiori* those in whom the heart is beating, but who make no effort at respiration—require, not permission to breathe, but the most energetic compulsion to do so; and it was with the idea of indicating a new method of such compulsion, to be used as a last resource, that I ventured to publish the case. I do not know whether intubation of the larynx, of which I have no experience, might replace the tracheotomy in the procedure.

I am, Sirs, yours &c.,

Tufnell Park, N., July 30th, 1887. CHARLES SCOTT WATSON.

AT Bolton a young lady has been poisoned through a chemist's mistake in dispensing a prescription. Hydrocyanic acid was used instead of hydrochloric acid. The jury returned a verdict of "Death from misadventure," and appended a strong censure upon the druggist and his assistant.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE NEWCASTLE ROYAL EXHIBITION.

THE attendance at our Exhibition must be considered very satisfactory—now approaching a million visitors. So far there has been no serious accident, but a female attendant ran a very serious risk the other day by touching an electric battery, from which she received such a severe shock that she has not yet recovered. The model dwelling house is now complete, and receives a large amount of attention from visitors. Mr. H. E. Armstrong has compiled a very useful guide, pointing out the sanitary points of the dwelling. The house is a permanent structure, and most of the materials have been given by the tradesmen of this city.

NEWCASTLE DISPENSARY.

Owing to the death of Dr. Holland a vacancy has taken place in the honorary medical staff of our dispensary. The selection in the first place is by a committee. Canvassing is prohibited, and also publication of testimonials in the public press, which is a great improvement on the former modes of election. An honorarium is attached to the post.

DURHAM COUNTY HOSPITAL.

A very sad occurrence took place on Monday last at the Durham County Hospital, when a nurse committed suicide by cutting her throat. The deceased was an American, and came to Durham some months ago. She attended to the out-door patients of the hospital, and was known all over the town as "Nurse Alice." Some time ago she became ill and depressed, and was admitted into the hospital for treatment.

NEWCASTLE INFIRMARY.

A very alarming accident took place near the Central Station in this city on Monday, when a collision took place in a workmen's train. About a score of the passengers were more or less injured, but I believe, with the exception of three cases, the injuries are fortunately not of a very serious nature.

A holiday "epidemic" has set in here "with some severity" among our *confreres*, and being somewhat under its influence, this will, I trust, sufficiently account for the brevity of my present communication.

Newcastle-on-Tyne, August 4th.

EDINBURGH.

(From our own Correspondent.)

ROYAL HOSPITAL FOR SICK CHILDREN.

THE managers of the Sick Children's Hospital have taken the action which it was anticipated they would adopt, and have instituted a permanent surgical division in the hospital arrangements. The re-arrangement of the wards to suit the new conditions is not as yet complete, but the appointment of surgeon to the institution has been already made, Mr. Joseph Bell having been appointed for a period of three years. Mr. Bell recently retired by rotation from the post of senior surgeon to the Royal Infirmary, where he had been teaching clinical surgery for fifteen years. The loss of his valuable services as a teacher was at that time generally regretted, and his present appointment to another teaching post will be received with a corresponding feeling of cordial satisfaction by all well-wishers of the Edinburgh School.

UNIVERSITY GRADUATION CEREMONIAL.

The annual Graduation Ceremonial in Medicine and Law took place on August 1st, when 55 graduates received the degree of M.D., and 199 those of M.B. and C.M., at the hands of Lord Inglis, Chancellor of the University. The honorary degree of LL.D. was in the first place conferred upon Professor Asa Gray, Dr. Gunning, the generous benefactor of the University, and Mr. Robey. Six of the theses presented by candidates for the degree of M.D. have been awarded gold medals for their high excellence. These are Dr. G. A. Atkinson's thesis on the Chemistry and Pharmacology of the Nitrites and Nitro-glycerine; Dr. A. Bruce's on the Developmental Anatomy of the Brain and Spinal Cord; Dr. John Gibson's on Waxy and Hyaline Degenerations; Dr. W. G. S. Miller's on the Myology of Seals; Dr. Philip's, on a Study in Phthisis, Etiological and Therapeutic; and Dr. Stevens' paper on Tests for certain Constituents of the Urine, and the Conditions in which they occur. The following scholarships and prizes were also presented:—The Murchison Scholarship in Clinical Medicine to Walter S. Colman; the Gunning Victoria Jubilee Prize in Chemistry to Hugh Marshall, B.Sc., for an experimental research in the Oxidation of Cobalt Salts by Electrolysis; the Ettles Scholarship to George Owen Carr Mackness, B.A., M.B., C.M., the most distinguished Bachelor of Medicine and Master of Surgery of this year; the Beaney Prize to Andre Arthman Bruere, M.B., C.M., and William Aldred Turner, M.B., C.M., equal; the Buchanan Scholarship to William Fraser Wright, M.B., C.M., and the James Scott Scholarship to John George Havelock, M.B., C.M. Professor Sir Douglas Maclagan delivered the address to the graduates.

THE PROMOTER'S ADDRESS.

Professor Sir Douglas Maclagan delivered the annual address to the graduates. He stated that this was the third occasion upon which, in due rotation with his numerous colleagues, the onerous and responsible duty had fallen to his lot. After a passing reference to the hazy prospect of a Universities Bill, which might have been his theme, but which had vanished for the present from the academic horizon, he set in order before his hearers the fields of professional life now opening before them, and indicated those spheres of labour and those landmarks of conduct which he desired they should choose. Commencing with civil practice, he described, in felicitous language and with apt and classic illustration, the pleasures and the sorrows incident to it; giving words of sound advice on the question of professional ethics, and expressions that may well be remembered with gratitude by his hearers in hours of difficulty and discouragement. Next, he considered the openings for professional work in the Services; and, taking up in the first instance the Navy, he drew a picturesque delineation of its main features, showing its advantages in the pleasant, useful, and healthful life which it affords, and adding a word of warning as to the dangers of letting slip the near view of the realm of medical progress which every member of the profession should strive to keep possession of. In turning to the consideration of the Army Medical Department, Sir Douglas Maclagan regretted that he had at present not much to say of an encouraging nature. This was a source of real vexation to himself as the son of an army medical officer, whose medal with its six clasps he preserved with filial pride, and who was entitled to say, in a more appropriate and befitting sense than their old friend Horace, "*Militari non sine gloria.*" He hoped, however, if it were ever his lot to address them or their successors on this topic, that he would be able to commend this branch of the service to their favourable consideration. After a few sentences devoted to the career of medical missionaries, to which some of his hearers had devoted their lives, he summed up his address in an eloquent appeal, setting forth the high ideal placed before the medical practitioner, and the noble and unvarying effort by which alone it can be attained.

Edinburgh, August 2nd.

DUBLIN.

(From our own Correspondent.)

BRITISH MEDICAL ASSOCIATION: DUBLIN MEETING.

THE Dublin meeting may be described as a conspicuous success, and an exceptionally large number of members have arrived in this city to take part in its proceedings. These include some very distinguished members of the profession resident in Italy, France, Switzerland, Germany, and America. The front hall over the entrance to Trinity College has been fitted up as a reception room, and is available for visitors; while a postal and telegraph office is

Digitized by Google

placed in the immediate vicinity for the use of the members. All the rooms required for the various meetings were provided in Trinity College. The Sections of Medicine, Surgery, Obstetric Medicine, Therapeutics and Pharmacology, and Pathology were held in the Medical School, and the remaining sections and sub-sections in the Museum buildings of the University. The President's address was delivered in the Dining Hall, and the general meetings were held in the Examination Hall, where also the addresses in medicine, surgery, and public medicine were delivered.

HONORARY FELLOWSHIPS.

At a meeting of the Royal College of Surgeons in Ireland on Wednesday, the 3rd inst., the Honorary Fellowship was conferred on Mr. J. Eric Erichsen, Mr. Jonathan Hutchinson, Mr. Charles Macnamara, Mr. Patrick Heron Watson, and Sir George Macleod. On the same day the College of Physicians formally conferred their Honorary Fellowship on Dr. Robert Barnes, Dr. Charlton Bastian, Sir Andrew Clark, Dr. William Tennant Gairdner, Dr. J. F. Charcot, Sir Dyce Duckworth, Dr. James Matthews Duncan, Sir William W. Gull, Dr. J. Hughlings Jackson, Sir George Edward Paget, Dr. Richard Quain, and Dr. Thomas Grainger Stewart. Sir Andrew Clark, Sir George Paget, Drs. Barnes, Bastian, Gairdner, and Stewart returned thanks.

MERCER'S HOSPITAL, DUBLIN.

Last week before the Vice-Chancellor, Mr. O'Grady sought for an injunction to restrain the governors and Dr. Knight from removing him from his position as senior surgeon and governor of the institution. On June 8th a notice of motion was given by Dr. Knight for a meeting of the governors on the 27th inst., to the effect that Mr. O'Grady be removed from his office. The Vice-Chancellor in delivering judgment said: "If he made the injunction, it would preclude absolutely the governors from holding the proposed inquiry. It would be the duty of the governors to investigate the facts, and form a decision in the exercise of their judgment, and for that decision they would be responsible to some tribunal." The application was therefore refused, the question of costs to stand over.

BELFAST.

(From our own Correspondent.)

THE LAGAN NUISANCE.

A DEPUTATION, representing the inhabitants of Cromac Ward, residing in the vicinity of the banks of the Lagan, appeared before the Harbour Commissioners of Belfast at their last meeting, and presented a memorial stating that the river Lagan is becoming more and more dangerous to public health, the stench in the mornings being quite unbearable, even as far as three-quarters of a mile from the river itself. The memorialists think the cleansing of the banks and bed of the river is most urgently required, and they ask the Harbour Board to do this. It was also stated (and I think with truth) that no drainage scheme, though carried out immediately, could bring the Lagan into a proper sanitary condition, unless the filthy matter so long allowed to accumulate is first of all removed. Among other speakers, Dr. Henry Bingham, Dr. Gibson, and Dr. Charles Kevin, all of whom practise in the neighbourhood of the Lagan, and who know well its present utterly abominable condition, urged strongly that the evil should be remedied. Sir Edward Harland, Bart. (the chairman of the Harbour Board), in replying to the deputation, remarked that the Board over which he presided were not a sanitary authority; but if they had the legal power they would be very glad to accede to the request of those present. He said, on behalf of the Harbour Commissioners, they would take means of communicating with the Town Council as to some joint action which should be legally taken in hand with a view to the removal of the mud banks. He thought they might look forward confidently to the banks being entirely removed, and he did not think it would be wise for them to wait until the whole drainage scheme should be completed. If the banks were cleansed by artificial means he did not think they would long remain so. It is hoped that action will soon be taken by the authorities, as the nuisance occasioned by the Lagan is at present extremely bad. Owing no doubt to the long drought, the smells have this summer penetrated to very long distances from the place in which they originate. On Monday last two deputations on the same subject appeared before our Town Council. The first wished to strengthen the opinion of the members of the Council, who were understood to be in favour of locks being placed on the river Lagan, while the second deputation, which represented 700 ratepayers, urged that steps should be taken to remove the mud banks. After a speech from the Mayor and a long discussion, it was decided to appoint a committee to take into consideration the prayers of the two deputations, and to confer with the Harbour Commissioners on the subject.

ST. JOHN AMBULANCE ASSOCIATION.

During the past few months classes in connexion with this useful Association have been conducted in Belfast by Dr. Mackenzie, Dr. S. Smith, and Dr. Lewers, and in Maghera by Dr. Harris. The number attending was large, and a great many were successful at the examinations. Dr. J. A. Lindsay is the local secretary, and it is owing to his energy that the interest in the Association in Belfast has been revived.

HOSPITAL FOR DISEASES OF THE SKIN.

The annual report presented at the meeting of the friends of this hospital (of which Dr. H. S. Purdon is honorary physician), held last week, shows that during the year 1149 patients were treated, being the largest number yet attended to in any one year. While the number of patients seeking relief is steadily increasing, the amount of the annual subscriptions is not increasing in proportion; but it is satisfactory to find that the donations from patients show a considerable increase. The treasurer's statement shows that the expenditure is very slightly greater than the income.

Belfast, August 3rd.

PARIS.

(From our own Correspondent.)

THE PASTEUR INSTITUTE.

THE statistical account of persons treated at the Pasteur Institute during the month of June has been published. As usual, the patients are divided into three classes. 1. Those bitten by animals proved to be rabid either by inoculation of the medulla or by the development of rabies in other individuals bitten. 2. Those bitten by animals proved to be rabid by veterinary observation. 3. Those bitten by animals suspected of rabies. It will be remembered that in the discussion at the Academy of Medicine concerning the cause of death in some cases brought forward by M. Peter, the partisans of M. Pasteur refused to admit the diagnosis of rabies when the proof positive had not been afforded by inoculation of the medulla. Applying, then, our system to the study of the Pasteurian statistics, if a clinical professor cannot diagnose rabies in man by bedside observation, and must wait until he has inoculated rabbits with his patient's nerve centres in order to know what is the nature of the disease, it stands to reason that a similar degree of certainty should be exacted for veterinary observations upon animals. M. Pasteur's categories of patients might then be reduced to two. 1. Persons bitten by animals proved to be rabid by inoculation. 2. Persons bitten by animals suspected of rabies by veterinary surgeons or others. The proportions the two classes bear to one another are as 10 to 1: in the June return 14 only of the patients out of 159 having been bitten by animals proved to have been rabid by inoculation. By far the greater number—113—belong to the category of those bitten by animals *proved* rabid by veterinary observation, a proof that we may accept with some reserve when it is offered concerning a method that has been backed by no inconsiderable amount of official pressure. Of the 159, 32 individuals are admitted to have been bitten by animals "suspected only of rabies"—which I take to be a euphemism for "unnecessarily frightened." Against these 159 saved from a more or less imaginary rabies, we have four new deaths, two of which are mentioned in the statistics, the other two in the public papers and in the *Journal de Médecine de Paris*. 1. Paul Hurot, bitten on May 30th, and treated from May 31st to June 13th; seized with rabies

Digitized by Google

July 1st. 2. Jules Bourgeot, bitten April 24th; treated from April 27th to May 16th; died July 11th. No charge is brought against this patient by the Pasteur Institute; but Hurot is said to have been an inveterate drunkard. 3. Desclide, bitten in May, died of paralytic rabies on July 21st, sixty days after the bite and forty-five after the end of the preventive treatment. 4. Gerde, bitten on March 27th, and treated at the laboratory for thirteen days from March 29th. On July 20th there was weakness in the legs, and the patient—a female servant—fell down. There was pain in the right arm and extreme weakness in both; also hydrophobia. The following day a white frothy liquid was vomited, and death took place without any other symptom than weakness.

CHARBON.

The *Semaine Médicale* publishes a letter from Professor Koch of Berlin correcting a statement made by M. Pasteur in his letter to the Imperial and Royal Society of Vienna concerning the opinion of the German school about vaccination against charbon. M. Koch says that they have by no means been converted in Germany to vaccination of cattle. If, in France, of the 200,000 sheep vaccinated annually, the mortality from charbon is only 1 per cent., whereas of the unprotected animals ten times as many die, on the other side of the Rhine the figures are very diverse. Six different series of experiments, collected by M. Schutz, professor at the Veterinary School of Berlin, have shown that the mortality is sensibly the same in vaccinated and unvaccinated animals, and the practice has been nearly entirely abandoned.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council of the College, held on Thursday last, Mr. J. B. Bailey was admitted to the office of Librarian. It was agreed that the museum and library be closed during the month of September.

The following report of the Committee of Management was read, and, after discussion, approved and adopted:—

That, in compliance with the request of the two Colleges, they have prepared a scheme for carrying out the examination for the Conjoint Diploma of Public Health, and have adopted the following recommendations on this subject to the two Colleges—viz.: 1. That the regulations relating to the examination, drawn up by the committee and accompanying this report, be adopted. 2. That for the present the examiners for the Diploma of Public Health be paid on the same scale as that adopted hitherto at the Royal College of Physicians—i.e., ten guineas for twelve or less than twelve candidates, and a capitation fee of four guineas for all candidates over that number. 3. That the Committee of Management be authorised to nominate, for election by the two Colleges, four examiners to conduct the examination in Public Health.

The Committee have carefully considered the letter of May 14th last from Mr. James Bankart and the accompanying memorial from several of the recognised provincial hospitals, calling the attention of the Colleges to the injury done to students entering at such hospitals by those regulations of the Examining Board in England which, by defining the intervals which must now elapse between the several examinations of the Board, no longer permit a whole year's attendance at the commencement of the student's career, on the practice of such hospital being counted as one of the required four years of professional study. On this subject the Committee have adopted the following as their report:—That this committee cannot recommend to the Royal Colleges any change in the regulation for the Conjoint Examinations, according to which the Colleges do not admit any candidate to either part of the Third or Final Examination till the expiration of two years after his having passed the Second Examination. That according to the second report of the Statistical Committee of the General Medical Council (p. 15) the average time occupied in medical study—between registration and the Final Examination—is approximately five years. That therefore it is still in the power of provincial hospitals to take a part in the training of students, not only by providing opportunities for acquiring professional knowledge before the commencement of the first year of study at a recognised medical school, but also by providing instruction in Chemistry, Chemical Physics, Materia Medica and Pharmacy, the required examinations in which may be passed in the preliminary period above indicated.

The Committee also submit the following recommendations for approval and adoption—viz.: 1. That candidates who withdraw from a part or parts of an examination for which they have sent in their names shall not be admissible to such part or parts until the expiration of six months, without the special permission of the Committee of Management. 2. That paragraph 9, Part II., of the scheme for constituting an Examining Board in England be amended so as to provide that the period occupied by the Oral and Practical Examination of each candidate on Materia Medica and Pharmacy be "not less than ten minutes," instead of "not less than fifteen minutes."

The Committee further suggests to the two Colleges the propriety of permitting portions of the Examination Hall, at times when they are not required for the examinations of the Examining Board in England, to be used by other institutions, especially those connected with medical education, on terms to be arranged by the Committee of Management.

The fifth report of the Committee on the Extension of the College Premises was read, approved, and adopted, and it was decided to spend £500 in repairs of the front of the College.

Sir W. MacCormac was appointed an Examiner in Surgery, in the place of Mr. Bryant, and Mr. Bryant was elected to fill the vacancy caused by the resignation of Mr. Hutchinson. Mr. Bryant was also elected a member of the Board of Examiners in Dental Surgery.

It was agreed that the annual meeting of the Fellows and Members be held on Thursday, Nov. 3rd, at 3 P.M. Further memorials, in opposition to the memorial of Dr. Wilks, were received from Mr. Bryan, and acknowledged.

The next quarterly meeting will be held on Thursday Oct. 13th.

Obituary.

ALEXANDER GORDON, M.D.

IT is with deep regret we announce the death of Dr Gordon, who for many years was the leading surgeon in Belfast and the north of Ireland. Although for some time he has not been in very robust health, his death was quite unexpected. On Thursday, July 28th, a short time after taking breakfast, he complained of a severe headache, and retired to bed, where, soon after, marked symptoms of cerebral hæmorrhage set in, from which in a short time he died in his sister's house at Saintfield, and, by a strange coincidence, in the same room in which sixty-nine years previously he was born. Dr. Gordon was a member of one of the oldest and most highly respected families in the north of Ireland. His father was a medical man in Saintfield, county Down, and on the church in that town there is a memorial stone (indicating that it was rebuilt in 1776) to which his grandfather's name, A. Gordon (treasurer), is appended. At the present time the brother of the deceased, Dr. Wm. Gordon, J.P., practises in Saintfield.

Dr. Alexander Gordon from an early age exhibited a decided taste for the study of medicine, and after having received his early education in Belfast and in Edinburgh, he took the M.D. of the latter university in 1841, when he was twenty-three; he also in the same year became a licentiate of the Edinburgh Royal College of Surgeons. Soon afterwards he began private practice in Belfast, and was appointed Demonstrator of Anatomy in the Royal Academical Institution, Dr. Drummond being at that time the professor. In 1847, on the death of Dr. Coffey, who lectured on surgery, Dr. Gordon was appointed to his chair; and in 1849, when Queen's College, Belfast, was opened, he was transferred to the new College as Professor of Surgery. Thomas Andrews, Dr. Burden, and Dr. Gordon were the only professors who had lectured in the old academical institution who were appointed in the new College. Dr. Gor

Digitized by Google

continued as Professor of Surgery in Queen's College until last summer, when, owing to failing health, and especially to defective eyesight, he found it necessary to retire. He was succeeded by one of his favourite pupils, Dr. Thomas Sinclair.

For a great portion of his professional life Dr. Gordon was surgeon to the Royal Hospital, and at one time he was president of the Belfast Pathological Society. During his long professional career he contributed many original papers to the medical journals. He wrote several articles on "Fractures of the Lower End of the Radius," and a "Treatise on the Fractures of the Lower End of the Radius, on Fractures of the Clavicle (and their treatment by a new clavicular apparatus), and on the Reduction of the Recent Inward Dislocations of the Shoulder Joint (by manipulation)." In this book many views peculiar to himself will be found, and in it the celebrated Gordon's splint (known all the world over) for the treatment of Colles' fracture is described, as well as an apparatus for treating fractures of the clavicle. He also wrote papers on "Fractures of the Thigh Bone," and on "A Peculiar and Unique Dislocation of the Femur upon the Pubes," &c. For a lengthened period he was a prominent member of the medical profession in Belfast, and from his close connexion with the medical school, he was brought intimately in contact with the students, on whom he had a very marked influence, owing to his great originality and independent character. He had a thorough knowledge of anatomy, and, while on nearly every branch of surgery he held original views, there were certain subjects which he was very fond of teaching. We question if any man has ever had a better knowledge of fractures, and he has left behind him, in the Pathological Museum of Queen's College, a collection which in number and variety is almost unequalled. Being of a mechanical turn of mind, he designed many ingenious forms of splints and other surgical apparatus. Hernia was another of his favourite subjects; in practice, he was almost always able to reduce such a condition, and he taught that the great majority of hernias could and should be put up without operation. It was his custom to spend the hour previously to his college lecture in the anatomical room, where, owing to the kindness of his friend and colleague (Professor Redfern), he utilised the opportunities afforded for teaching surgical pathology. It was here that the thoughtful student was so impressed with Dr. Gordon's wonderful tactile powers, with his great originality, and with his accurate knowledge of surgical anatomy. When the British Medical Association visited Belfast in 1884, Dr. Gordon was asked to take part in a discussion in the medical section on a favourite subject of his—chronic rheumatoid arthritis. He produced on those present a marked impression by the specimens of this condition which he exhibited, and by the originality of his views on a subject which, as he said, he had been studying for thirty years. He had a very large consulting practice; indeed, his opinion was almost invariably sought by anyone in the north of Ireland who had a surgical affection. He was popular with the students, who respected him as a man who who had a thorough grasp of the subjects he taught, and who, in every department of surgery, had views original to himself and different from the stereotyped teaching of the ordinary text-books. A fine portrait of him (presented by his students) is placed in the Examination Hall of Queen's College, Belfast.

Dr. Gordon was a man utterly destitute of all cant. In private life those who came in contact with him could not fail to be impressed by his great simplicity of character, by his sterling honesty, and by the freshness and originality of his views on almost every subject. He was very fond of a country life, and several years ago he built a residence on some property which he owned near Comber, on the margin of Strangford Lough. Here during the summer it was his custom to reside from Saturday to Monday, although he was not allowed to be free from professional duties, as on these days large numbers of the country people came to get his opinion. He was interred on Saturday last in Saintfield Church-yard, within a short distance of the historical ground where in '98 the battle of Saintfield was fought. The funeral was private, but, in addition to his own relatives, a few of his personal professional friends (all of them former pupils) were present, and helped to carry to his last resting-place the remains of one for whom they had the most profound respect. Dr. Gordon leaves a widow, a son, and one daughter.

DR. ANDREW FERGUS,

OF GLASGOW.

WE regret to announce the death of Dr. Andrew Fergus of Glasgow. Dr. Fergus was born in the year 1822, in the town of Newcastle, where his father was minister of the Scotch church. He was a student at King's College, London, and at Glasgow University. Like several other distinguished men, he was a pupil of Messrs. Greenhow and Ingham of North Shields. After obtaining the diploma of the Royal College of Surgeons of England he commenced practice in Glasgow, and in the year 1866 he obtained the M.D. of the University of Glasgow (*honoris causâ*). On three different occasions he was elected president of the Faculty of Physicians and Surgeons of Glasgow, and under his auspices, and mainly through his influence, the Faculty abolished its single diploma and united with the Edinburgh corporations to grant the triple qualification. While he was president, also, the Faculty instituted an examination for the Fellowship. For three years he was president of the Philosophical Society of Glasgow. Since the opening of the Western Infirmary he had been a representative of the Faculty at the Board of Managers, and latterly was convener of the Medical Committee. Ten years ago he was chosen by the Queen to be her representative for Scotland on the General Medical Council, and at the expiry of his term of office he was reappointed. He was also president of Anderson's College, and took a great interest in the formation of the West of Scotland Technical College.

In all his public positions Dr. Fergus's opinion was much valued, for he combined great sagacity with excellent business tact, so that everything left to his charge was well and efficiently done. As a practitioner he was much loved and respected by his patients, and had gathered around him the leading families in Glasgow and the west of Scotland. He had also a large consulting practice, and having the very essential advantage of being a general practitioner, he was justly considered an all-round man, and his advice was sought for in almost every variety of circumstances. As a scientist he gained deserved fame from his careful investigations on the action of sewer gases on the water supply, and successfully demonstrated at a meeting of the Philosophical Society how they exercised a deleterious influence on leaden pipes.

From the sketch of his life thus given it is easy to understand how much his death is lamented by all who knew him. The city of his adoption mourns, and the grief may be said to be universal, for in his long and active career Dr. Fergus had made many friends among the rich and the poor. As a physician and citizen his record is very clear and unstained. He lived an upright life. He was an affectionate husband, a wise father, and in all the prominence of the exalted positions he occupied he was a worthy and exemplary public servant, and a thorough representative of the profession he adorned. He is survived by a widow, one daughter, and three sons. The eldest son is worthily following in his father's footsteps as a medical practitioner; the second is a surgeon-dentist; and the youngest is a distinguished alumnus in medicine of the University of Glasgow.

W. CONNER LYSAGHT, M.R.C.S., L.R.C.P. LOND.

MR. W. CONNER LYSAGHT entered as a student of the Bristol Medical School in 1879. In the course of his studies he showed much assiduity in his work, and his successes at the school prove his ability to have been above the average. He held the post of assistant demonstrator of anatomy, and, after qualifying, became medical tutor during 1885-86. In this latter capacity his qualifications as a teacher and governor became apparent, and his kindly and courteous manner won the respect of those with whom he had to deal. So recently as June last Mr. Lysaght was elected to fill the post of assistant resident medical officer to the Bristol Royal Infirmary, and, although his tenure of office was so short, it was sufficiently long to show that the earlier indications of his professional skill and enthusiasm had not been falsely represented. On July 17th, Mr. Lysaght manifested the earlier symptoms of scarlet fever, which unfortunately pursued a malignant course, and ended fatally on July 24th. Whether this illness was contracted from a patient on whom

Digitized by Google

he had performed tracheotomy some days previously, and in which case he considered it necessary to apply his lips to the wound in order to suck out the blood from the trachea, or whether he simply "caught" it among the out-patients, it is difficult to say. Any way, he died at his post and in the execution of his duties—died honourably, and died esteemed and regretted by all who had had the pleasure and honour of knowing and working with him.

CESARE BRAICO.

IN the history of the Italian war of independence—the "risorgimento," as it is called—few chapters are more interesting than that which describes the part taken in it by medical men, of whom not the least deserving and conspicuous was the able physician whose name is given above. He was born in the Kingdom of the Two Sicilies, at Brindisi in 1822, and he early devoted himself to the study of medicine in the Neapolitan School. He had barely graduated when he became politically "compromised," and in company with patriots like Spaventa, Poerio, and Settembrini, he shared the weary horrors of a Bourbon prison, from which, however, unlike his comrades in adversity, he was fortunate enough to effect his escape. He fled to England, and, like Pantaleoni, employed himself in professional study and in the occasional furtherance of patriotic schemes till 1859, when the policy of Cavour set the cause of Italian unity on wheels. At Turin he became known as one of the most fearless of the "party of action," and thence he passed to Genoa; from Genoa, as one of Garibaldi's "Thousand," to Quarto, and thence again to Marsala.

Braico was a right-hand man of Bertani in the care of the sick and wounded, and so frequently in aiding the latter did he venture under fire that he had on eleven occasions to fight like a common combatant to extricate himself from a position of jeopardy. Singularly enough, his wounds were never more than of the slightest, even when on the famous 1st of October, 1860, at Capua, he earned the praise of Garibaldi for heroism shown in the grand assault, when hundreds of red-shirts were falling around him. When Italy was proclaimed a kingdom in March, 1861, his fellow townsmen of Brindisi elected him as their representative in the parliament just assembled at Turin. Then in the peaceful arena of debate, he encountered many of his old comrades of the prison and of the battle field, and again made himself conspicuous as alternately the opponent or the auxiliary of Cavour or Garibaldi, Poerio or Crispi, Spaventa or Cavioli, Fanti or Bertani, Ricasoli or Nicotera.

Like Bertani, he distinguished himself in all legislation connected with the public health, and in recognition of his services in this department he was made "Presidente del Consiglio superiore di Sanità" at Naples. After years spent in the effective discharge of the duties of this post he was called to Rome to act as superintendent of State archives; but he did not long enjoy the comparative ease of this tranquil berth. Symptoms of failing mental power rapidly declared themselves, and he had to be removed to the Manicomio on the Janiculan, where he died on July 27th, in the sixty-fifth year of his age.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following candidates having conformed to the bye-laws and regulations, and passed the required examinations, were admitted Licentiates of the College:—

Alexandre, John Francis Gaston, St. Bartholomew's Hospital.
Althorp, Charles Frederick Manning, St. Paul's-road, Bradford.
Arnison, William Drewill, Allensdale-town, Northumberland.
Ashworth, P., Delauney-road, Higher Crumpsall, Manchester.
Bannister, Marmaduke, Acomb-street, Manchester.
Barber, Frederick Samuel, Broomfield-terrace, Bradford.
Barret, Edward E., Springfield-road, St. John's Wood.
Birch, Charles Ormond, Harley-street.
Booth, George, Low Pavement, Chesterfield.
Bright, Archibald Leonard, St. Bartholomew's Hospital.
Bullivant, Samuel, Gordon-street.
Bury, Frederick C., Upper Brook-street, Manchester.
Bullock, Henry Maurice, St. Thomas's Hospital.
Caddy, Arnold, St. George's Hospital.
Close, John Borrill, Fulham-road, South Kensington.
Cook, Samuel Bird, Ivydale-road, Nunhead.
Cort, John Giles Denison, Charing-cross Hospital.
Cosens, Charles Hyde, Huntley-street, Bedford-square.
Crisp, Ernest Henry, Marlborough House, Balham Hill.
Dane, Harold, Finchley-road, Hampstead.
Davies, Albert Barnes, Frederick-place, Mile-end-road.
Davies, Hughes Reid, Hill-street, Rutland Gate.
Day, E. Irving, Endsleigh, Dunheved-road, Thornton Heath.
De Lisle, Albert, St. Bartholomew's Hospital.
Dixon, Charles Harvey, St. Mary's Hospital.
Drake-Brockmann, Herbert Edward, St. George's Hospital.
Ellison, E. H., Daleiren-road, Amhurst Park, Stamford Hill.
Evans, William Norman, Thurlow-road, Hampstead.
Field, Oliver, Battledown Gates, Cheltenham.
Fisher, Thomas Hammond, Manchester-road, Stockport.
Fisher, William Featon, Pembridge, Isle of Wight.
Fowler, Thomas Webb, Wycombe House, Coventry.
Fox, Frederick G. Townsend, St. Bartholomew's Hospital.
Gilford, Hastings, Beech-grove, Redhill.
Gilpin, William J., Harrington-street, Regent's Park.
Godfrey, Thomas Henry, Billing-road, Northampton.
Gould, John Edwin, Albert-street, Regent's Park.
Green, George Sydney, Kildare-terrace, Westbourne Park.
Hamel-Smith, Lionel, Sydenham-road, Croydon.
Harries, William, Stanhope-street.
Harris-Liston, Llewellyn, University College Hospital.
Hastings, Edwin Birchall, Denmark-hill, Wimbledon.
Hendley, Arthur Gervase, St. Bartholomew's Hospital.
Hitchings, Robert, Groombridge-road, South Hackney.
Hubbard, Walter Lovett, The Grove, Clapham-road.
Joberns, William, The Grange, Aldridge, Walsall.
Johnston, Arthur Hammersley, Jamaica-road.
Kanthack, Alfredo Antunes, St. Bartholomew's Hospital.
Kelsall, Henry Trueman, London Hospital.
Larcombe, S. Slee, Cliftonville, Selsdon-road, West Norwood.
Lotz, Henry John, St. Thomas's Hospital.
Luard, Hugh Bixby, St. Thomas's Hospital.
Lubbock, Edgar Ashley, London Hospital.
Mair, Ludovic William Darra, St. Bartholomew's Hospital.
Nixon, John, St. Bartholomew's Hospital.
Parker, Frederick William, Brussels-road, New Wandsworth.
Phillips, G. Gordon Owen, Castletown-road, West Kensington.
Pound, Clement, Odiham, Hampshire.
Puddicombe, Edward Leonard, St. George's Hospital.
Rust, John, St. Bartholomew's Hospital.
Savery, Frank, Hastings Cottage, Grange Park, Ealing.
Savory, William Harmsworth, Douglas-road, Canonbury.
Skill, James Maurice, St. George's Hospital.
Solly, Reginald Vaughan, St. Thomas's Hospital.
Tanner, Charles Price, Houghton-place, Ampthill-square.
Theobald, Owen Le Mare, Manor-road, Holloway.
Thistle, William Brown, Stratford, Ontario, Canada.
Vernon, Arthur Heygate, St. George's Hospital.
Walker, James Pixton, Manchester.
Wilde, Leonard, Ebury-street, London.
Williams, William Griffith, Vincent-terrace, Colebrooke-row.
Wood, Hubert Moody, Barry-road, Dulwich.
Wooldridge, Arthur Tylee, Christchurch-road, Winchelsea.
Wordsworth, William John, Charlotte-street, Portland-place.
Wright, William Luard, Cambridge-terrace, Hyde Park.

The following officers have been elected in addition to those enumerated in our last issue:—Finance Committee: Sir Edward Sieveking, M.D.; G. Tupman Fincham, M.D.; C. J. Hare, M.D. Examiners: Chemistry and Chemical Physics: C. H. Ralfe, M.D.; A. J. Bernays, Ph.D.; W. J. Russell, Ph.D.; August Dupré, Ph.D.; William Foster, F.C.S. Materia Medica, Medical Botany, and Pharmacy: J. Mitchell Bruce, M.D.; Frederick Taylor, M.D.; D. Bridge Lees, M.D.; William Murrell, M.D.; Nestor Isidore C. Tirard, M.D. Elementary Physiology: William Ewart, M.D.; Vincent Dormer Harris, M.D. Physiology: W. H. Allchin, M.B.; Leonard Wooldridge, M.D.; Professor Schäfer. Osteology and Anatomy: John Curnow, M.D.; Henry Morris, F.R.C.S., L.R.C.P. Medical Anatomy and Principles and Practice of Medicine: Lionel Smith Beale, M.B.; W. H. Stone, M.B.; Octavius Sturges, M.D.; H. Gawen Sutton, M.B.; W. Butler Cheadle, M.D.; P. H. Pye-Smith, M.D.; Sir Dyce Duckworth, M.D.; H. Charlton Bastian, M.D.; William Cayley, M.D.; T. Tillyer Whipham, M.B. Midwifery and Diseases peculiar to Women: W. Overend Priestley, M.D.; Henry Gervis, M.D.; A. Lewis Galabin, M.D.; F. H. Champneys, M.B. Surgical Anatomy and Principles and Practice of Surgery: George Pollock, F.R.C.S.; Sir William Mac Cormac, F.R.C.S.; W. Morrant Baker, F.R.C.S.; Professor Humphry, F.R.C.S. Hygiene: Thomas Stevenson, M.D.; Edward Ballard, M.D.; Richard Thorne Thorne, M.B.; W. H. Corfield, M.D.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary ex-

Digitized by Google

aminations for the diploma were at an ordinary meeting of the Council on the 4th inst. admitted Members of the College:—

Alexandre, John Francis Gaston, St. Bartholomew's Hospital.
Althorp, Charles F. Manning, St. Paul's-road, Bradford.
Archer, Ernest Richard Barnes, Trinity-square.
Ashworth, Percy, Delauney-road, Crumpsall, Manchester.
Bannister, Marmaduke, Wellington-street, Blackburn.
Barrett, W., Nile-street, Stockport-road, Ashton-under-Lyne.
Bennett, George Herbert, Windsor Villa, Plymouth.
Bird, Matthew Mitchell, Gloucester-road, South Kensington.
Bright, Archibald Leonard, St. Bartholomew's Hospital.
Brooks, Richard Philip, Tollington Park.
Bullivant, Samuel, Gordon-street.
Bullock, Henry Maurice, Overtown House, Isleworth.
Bury, Frederick Charles, Upper Brook-street, Manchester.
Caddy, Arnold, Redcliffe-square.
Carter, Arlingham, Wellington House, Gloucester.
Cole, Francis, Leadenhall-street.
Cook, Samuel Bird, Ivydale-road, Nunhead.
Cooke, Cecil Whitehall, St. George's-terrace.
Cordiner, Richard, East Heslerton, York.
Cort, John Giles Denison, Princes-street, Blackburn.
Crisp, Ernest Henry, Marlborough House, Balham Hill.
Dane, Harold, Finchley-road, Hampstead.
Davies, Albert Barnes, Frederick-place.
De Lisle, Albert, Great Ormond-street.
Drake-Brockmann, Herbert Edward, Hauteville, Guernsey.
Dunlop, James Crawford, Alva-street, Edinburgh.
Essery, William Joseph, Osborne House, Gunnersbury.
Field, Oliver, Battledown Gates, Cheltenham.
Godfrey, Thomas Henry, Billing-road, Northampton.
Gould, John Edwin, Albert-street, Regent's Park.
Hands, Charles Hubert, Deddington, Oxon.
Harris, William, Notts-square, Carmarthen.
Hastings, Edwin Birchall, Denmark Hill, Wimbledon.
Heatley, William, Grafton-street.
Hendley, Arthur Gervase, Crosfield, Bentley, Hants.
Hensley, Philip Henry Sandybrooke, Beaumont, Jersey.
Herring, Herbert Thomas, Spring-grove, Hampton-on-Thames.
Hewan, John, Belgrave-road.
Hill, Edward Brereton, Longfleet, Poole, Dorset.
Hoole, John, Maitland Park-road.
Hubbard, Walter Lovett, The Grove, Clapham-road.
James, John Angell, Bridgetown, Stratford-on-Avon.
Johnston, Arthur Hammersley, Jamaica-road.
Larcombe, Samuel Slee, Cliftonville, West Norwood.
Lewis, Ernest Edward, Middlesex Hospital.
Lewis, Phillip King, Adelaide-road.
Lotz, Henry John, St. Thomas's Hospital.
Luard, Hugh Bixby, Lambeth Palace-road.
Maddox, Ralph Henry, Kirkheaton Rectory, Huddersfield.
Mair, Ludovic William Darra, Ledbury-road, Bayswater.
Marriott, Henry Tancred, Milner-street, Chelsea.
Mills-Roberts, Robert Herbert, Erllfair Blaenan, Festiniog.
Nash, Walter Gifford, Clavering, Newport, Essex.
Norton, John, The Chestnuts, Staplegur, Taunton.
Owen, David, Fenwick-street, Hulme, Manchester.
Phillips, Stanley Clyde, Victoria-place, Plymouth.
Puddicombe, Edward Leonard, St. George's Hospital.
Raby, Leonard, Treviddoe, Liskeard, Cornwall.
Roberts, Alfred Ernest, Upminster, near Romford.
Robinson, Frederick William, Granville House, Huddersfield.
Richardson, Wm. George, Copfield House, Gateshead-on-Tyne.
Rigg, Vincent John, Hartington-place, Eastbourne.
Savery, Frank, Grange Park, Ealing.
Savory, William Harmsworth, Douglas-road, Canonbury.
Smith, Edward Locke Cathcart, Blenheim-crescent.
Solly, Reginald Vaughan, St. Thomas's Hospital.
Stewart, Robert Wray, Hatherley-grove, Bayswater.
Stokes, John, Shoreham-street, Sheffield.
Tanner, Charles Price, Ampthill-square.
Theobald, Owen Le Mare, Manor-road, Holloway.
Thompson, Alfred William, Queen's-road, Birmingham.
Tidy, Stewart Alexander, "Glenelg," Springfield Park, Acton.
Tordoff, Sargen, Louis-street, Leeds.
Trevelyan, Basil Riddell Trevelyan, Coombe Down, Bath.
Watkins, Frank Augustus, Stowe Park.
Walker, James Piton, Great Ducie-street, Manchester.
Waterhouse, Herbert Furnivall, Roy. Med. Soc., Edinburgh.
Wawn, Edward Russell, Kirkleatham Vicarage, Redcar.
Williams, William Griffith, Nag's Head, Corwen.
Wood, Hubert Moody, Barry-road, Dulwich.
Woodward, William, Hill Park-crescent, Plymouth.

BRITISH MEDICAL SERVICE.—The following is the list of Surgeons on Probation in the Medical Department of the British Army who were successful at both the London and Netley examinations recently held. (The prizes are awarded for marks gained in the special subjects taught at the Army Medical School.) The final positions of these gentlemen are determined by the marks gained in London added to those gained at Netley:—

	Combined Marks.		Combined Marks.
Smith, H. E. H.	6195	Blenkinsop, A. P.	4975
*Gore, Graham W. P. ...	6150	Paterson, J.	4905
Alexander, G. F.	5860	Davoren, V. H. W. ...	4905
Spong, C. S.	5855	Wright, A.	4900
Leishman, W. B.	5850	Copeland, R. J.	4815
Woods, E. M.	5705	Girvin, J.	4780
Thomson, J.	5655	Luther, A. J.	4725
Rawnsley, G. T.	5460	Peeke, H. S.	4700
Reilly, O. W.	5200	Borradaile, A. L.	4600
Freeman, E. C.	5125	Smyth, R. H.	4575
Trask, J. E.	5120	Birt, T.	4555
Crofton, W. J.	5065	Hallaran, W.	4545
Forbes, N. H.	5065		

* Gained the Montefiore Medal and Prize of 20 guineas.

INDIAN MEDICAL SERVICE.—The following candidates were successful at the recent examinations:—

	Marks.		Marks.
Meyer, C. H. L.	6495	Fischer, L. G.	5505
Elliott, W. H. W.	6230	Vost, W.	5450
Murray, J.	6170	Garvie, J.	5275
Childe, L. F.	6135	Mc Evoy, W. G.	5250
Clark, W. R.	6130	Gilbert, C. E. L.	5240
Braide, G. F. W.	6080	Macleod, H. W. G.	5055
Marks, R. J.	5985	Manifold, C. C.	5045
Sunder, C. E.	5810	Irvine, G. B.	4950
Ker, M. A.	5755	Crawford, F. J	4870
Herbert, H.	5695	Simpson, D.	4860
Parry, T. D. C.	5575	Robertson, R.	4795
Jolliffe, A. R.	5560	Moore, T. C.	4770
Buchanan, A.	5550	Jacob, A. H.	4670
Hailey, P. O. W.	5545	Karney, W. H.	4645

Mr. Meyer gained the Herbert Prize of £20, with the Martin Memorial gold medal; Mr. Marks gained the prize in Pathology, presented by Sir Joseph Fayrer; Mr. Elliott gained the Montefiore second prize; and Mr. Murray gained the Parkes Memorial bronze medal.

THE Library of the Obstetrical Society of London will be closed from August 15th to September 15th.

THE seventh annual meeting of the Ontario Medical Association was held at Toronto on the 8th and 9th ult.

AN attempt is being made to establish a permanent Hygienic Museum in Warsaw.

THE Provincial Council of Antwerp has decided against the erection of a large provincial lunatic asylum.

IT is proposed to present Professor Alexander Williamson, F.R.S., with his portrait on the occasion of his retirement from the chair of Chemistry in University College.

AT a meeting of the representatives of the various local authorities in the Stourbridge Union on the 19th ult., it was decided that a hospital for infectious diseases be provided without the formation of a separate hospital board.

SUNSTROKE.—The excessively high temperature in Austro-Hungary has been attended with many cases of insolatio. In Buda-Pesth, sixteen gendarmes are said to have been prostrated by the heat, and placed under medical care.

THE jubilee bazaar in aid of the funds of the Kent and Canterbury Hospital closed at Canterbury on the 29th ult. The proceeds of the sale, including several donations, amount to upwards of £1400. The main portion of the deficit which it was hoped to pay off will therefore be met.

INTEMPERANCE IN BELGIUM.—A law consisting of sixteen articles has just been passed in Belgium with the object of checking alcoholic excesses. One of the clauses provides for the periodical examination of the character of the holders of licences and their mode of doing business, and another clause prohibits the giving of credit for drink.

MANCHESTER ROYAL INFIRMARY.—The annual meeting in connexion with this infirmary, and the affiliated institutions, was held on the 28th ult. From the report which was presented and adopted, it appeared that in 1876 the total number of persons treated at the infirmary and at the convalescent hospital amounted to 21,061, and the cost was £25,116. In 1886-87 no less than 37,548 patients received treatment, at a cost of £22,596. Thus the increase in the number of patients amounted to over 78 per cent., but the actual expenditure decreased £2520, or 10 per cent. The financial report was not satisfactory, the deficit last year amounting to £2855, and that of the present year to £2459.

Digitized by Google

ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.—The directors of this institution have unanimously resolved that one of the wards of the hospital shall be specially set apart for the treatment of surgical cases, and that this arrangement shall subsist for a period of three years from and after November 1st next, and at the expiry of that time shall be subject to reconsideration. Dr. Joseph Bell has been appointed surgeon of this ward.

HYPNOTISM is said to be making great advances in France, where people are now being mesmerised for all sorts of diseases, and even bad habits. The latest outcome has been the attempted curing of the drink habit by what is called "suggestion," the patient, while "under control," being ordered to avoid intoxicating liquors of all kinds, and it is claimed that success has been obtained in this respect.

THE CULTIVATION OF IPECACUANHA.—The Madras Government, on the recommendation of its Surgeon-General, has determined to commence the cultivation of ipecacuanha on a small scale in the Nilgiris. The experiments at Ootacamund have shown that the plant, although not difficult to propagate, can only be successfully grown in a limited area possessing suitable climatic conditions; and it was considered unlikely that the cultivation would be taken up to any extent by private individuals.

MEDICAL MISSION AT NAZARETH.—Dr. Vartan, who has for many years acted as the agent of the Edinburgh Medical Missionary Society at Nazareth, has been engaged in building a permanent hospital, so as to be able to carry on his work more effectively. Recently, however, he has been obliged to give up the site and all the buildings to the Turkish Government. This has of course been a great disappointment to him and to all the friends who have contributed towards the work; but there is still hope that another site may be found, and the requisite firman obtained from the Turkish authorities.

ST. GEORGE'S HOSPITAL.—Dr. John W. Ogle on Wednesday, the 27th ult., distributed the prizes in the medical school of this hopital. The examinations passed by the successful candidates were extremely satisfactory, as the number of marks awarded by the different examiners amply testified. In a few prefatory remarks, Dr. Ogle recounted his experience, both in the hospital and in its school, in years gone by, and called the attention of his audience more especially to the many advantages they possessed over students of former days. He urged them strongly to perfect their knowledge of their profession by diligent study of its practice in the wards, and urged upon them the mental training which an examination afforded, even should the competitor be unsuccessful in obtaining the prize. The following prizes were then awarded:—General Proficiency Prizes: 1st year, Mr. R. M. H. Walford; Honorary Certificate, Mr. A. W. Read; 2nd year, Mr. L. W. Seymour; 3rd year, Mr. Cyril Ogle. Certificate of Proficiency in Medicine, Pathology, and Midwifery: Mr. H. Higgins. Treasurer's Prize, and the Brackenbury Prize in Surgery: Mr. F. W. Parker. Thompson Medal: Mr. A. H. Ward. Pollock Prize in Physiology: Mr. L. W. Seymour. Henry Charles Johnson Prize in Anatomy: Mr. Barkworth. Brackenbury Prize in Medicine, and William Brown Exhibition (£40): Mr. E. le Cronier Lancaster. Sir Charles Clarke's Prize: Mr. H. E. Drake-Brockman.

MEDICAL NOTES IN PARLIAMENT.

Smoke Nuisance Abatement (Metropolis) Bill.

IN the House of Lords on the 1st inst., Lord Stratheden and Campbell moved that the House go into committee on this Bill.—Lord Wemyss moved, as an amendment, that before the law for the prohibition of smoke was extended to private dwellings it was desirable that the purpose and intention of the Acts relating to smoke nuisance should be more fully carried into effect, either by their amendment or by their better administration.—The Lord Chancellor objected to the powers to be left to the local authorities as unprecedented. The object was a good one, but the Bill was ill-digested, clumsy, and inconvenient, and he believed it would be inoperative.—Lord Monkswell thought that some of the objections made to the Bill were not well founded, because the Home Secretary could revise the penalties.—Lord Crawford was of opinion that some of the provisions relating to private houses would be intolerable.—Lord Hobhouse supported the Bill, and Lord Brownlow opposed it.—Lord Rosebery believed that the better course in this matter would be to give to the metropolis a body to manage its municipal affairs and to let that body deal with the smoke nuisance; but, as their lordships had read the Bill a second time and referred it to a Select Committee, he thought that to adopt the amendment would be to show a disregard, if not a contempt, for former decisions of the House.—Lord Denman spoke in favour of the amendment.—On a division, the motion for going into committee was rejected by 30 to 12.

The Margarine (Fraudulent Sale) Bill.

On the 2nd inst., on the order of the day for going into committee on this Bill, Lord Wemyss rose and appealed to Lord Basing to postpone the Committee on the ground that the report of the Select Committee of the House of Commons on the subject of the Bill had only just come into their lordships' hands. This suggestion gave rise to an animated discussion, in which Lord Wantage, Lord Granville, Lord Bramwell, Lord Rosebery, and Lord Thring supported Lord Wemyss; and Lord Powerscourt, Lord Egerton, Lord Milltown, Lord Stanley of Preston, Lord Basing, and Lord Fitzgerald opposed him. Ultimately Lord Cranbrook recommended Lord Basing to move that the House go into committee. This Lord Basing did, and the motion was carried by 50 to 15.—Their lordships having gone into committee, Lord Granville announced that the minority in the division just taken would refrain from taking any part in discussing the Bill until it reached another stage. The various clauses, with some unopposed amendments, were ordered to stand part of the Bill, and the preamble and the title were agreed to.

Fever at the Gold Coast.

In the House of Commons, on the 26th ult., in answer to Mr. Conybeare, Sir H. Holland said that "black water fever" was not a specific disease, but was a name given by certain doctors on the Gold Coast to a specially severe form of the ordinary remittent fever of West Africa. The rainy season this year had no doubt been more than usually unhealthy, but there was no reason to attribute this in any special way to want of good sanitary arrangements and good water. Indeed, the papers recently laid before Parliament (C. 5071, pp. 104 and 241) showed that a great deal had been done in the way of improvement in these matters, and the efforts of the Government were being continued. The statement that 50 per cent. of the European residents had died, was, he had every reason to believe, greatly exaggerated. He had received no report of the election of a Board of Health at Cape Coast, or of any petition to the Governor on the subject.

Drainage in North-west London.

In answer to Mr. Bartley, Mr. Ritchie said that the Local Government Board had not received any complaint as to the drainage arrangements of the Hendon sanitary authority at Alperton. If any such complaint were made to the Board it would receive attention. He added that the Board had that day received a letter from the sanitary authority in which they entirely deny that the works are carried on in a satisfactory manner.

Ventilation of the House.

In reply to Mr. Warmington, Mr. Plunket said that his attention had been from time to time directed to the offensive smells prevalent in the House and its corridors, and very recently. He was perfectly satisfied that they did not proceed from any defect in the drainage of the palace, which is, he believed, now in as perfect a state as modern science could make it. He had no doubt that these smells came from outside. Observations were being made, but they had not yet been able to trace the smells to their true origin.

On the 1st inst. Mr. Esslemont asked the First Commissioner of Works whether he had any reason to believe that the noxious air in the House was due to the artificial system of ventilation; and whether, by way of experiment, he would allow the present system to be discontinued for a few days in order to allow fresh air to be admitted from the windows in the roof.—Mr. Plunket said he had no reason to believe that the air in the House was noxious, and what the hon. member called the artificial system of ventilation consisted simply in this—that the air which members had been breathing was drawn out through the ceiling so that fresh air might constantly enter the more freely from below. He could not advise that the experiment suggested by the hon. member of discontinuing this system should be tried.—In reply to a further question by Dr. Kenny, as to whether the suggestion made by the hon. member for Mid-Cork as to straining the air introduced into the House had been taken into consideration, Mr. Plunket said that such experiments had been tried.

Metropolitan Cemeteries.

On the 2nd inst., Mr. O. V. Morgan asked the Secretary of State for the Home Department, with regard to the proposed new burial ground for South London, whether he was aware that the cemeteries of Bethnal-green and Victoria-park, and of Stoke Newington at Abney-park, were sanctioned without application to Parliament; whether he was aware that by 16 and 17 Vict., c. 134, s. 6, it was enacted, "When any new site has been selected an ordinary letter stating the fact and requesting approval of the same shall be addressed to the Home Secretary;" whether he was aware that the Battersea Burial Board was prepared to carry out any suggestions he might make as to sanitary arrangements; whether he was aware that the chairman of the Sutton Local Board advocated the establishment of the cemetery as a great boon to the inhabitants of that town; and whether he was now prepared to give his sanction to the proposed cemetery.—Mr. Mathews replied that the cemeteries named in the hon. member's question were, he believed, formed under the powers of the Cemeteries Clauses, 1846. The 16 and 17 Vict., c. 134, did not, so far as he could discover, contain the words quoted by the hon. member. His answers to the third and fourth questions was in the negative. The opening of a new burial ground and burials in Sutton had been prohibited by Order in Council, for the protection of the public health; and he was still considering whether he was justified in sanctioning the opening of a new and large cemetery in that district, as to which he was now receiving frequent communications.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BACON, ALFRED T., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Sixth District of the Leeds Union.

BARKER, JOHN, M.B.Durh., M.R.C.S., has been appointed Medical Officer of Health for the Reeth Rural Sanitary District; and Medical Officer and Public Vaccinator for the Muker District of the Reeth Union, vice Turner, resigned.

BRIDGMAN, HENRY EDWARD, L.R.C.P.Lond., M.R.C.S., has been appointed Assistant Surgeon to the Burton Infirmary.

CLARKSON, EDWARD, L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Fourth District of the Ongar Union.

EVANS, EVAN, M.R.C.S., L.S.A., has been appointed Medical Officer for the Llanelly District and the workhouse of the Llanelly Union.

HOOPER, ALFRED, M.R.C.S., L.S.A., has been appointed Assistant Surgeon to the Burton Infirmary.

JACK, CHARLES, M.D., C.M.Glas., has been appointed Medical Officer of Health for the Horsforth Urban Sanitary District.

JOHNSTONE, WILLIAM, has been appointed Analyst for the Borough of St. Ives.

LODGE, SAMUEL Jun., M.B., B.S., has been appointed Medical Officer of Health for the Tong Urban Sanitary District, vice Lodge, resigned.

MATTHEWS, VALENTINE, M.R.C.S., L.S.A., has been appointed Surgeon to the Westminster General Dispensary.

MONTAGUE, A. J. HELM, M.B.Dunelm., L.R.C.P.Lond., M.R.C.S., has been appointed House-Surgeon to the East Suffolk and Ipswich Hospital, vice Taylor, resigned.

MORGAN, G. F. ELLIOT, M.R.C.S., L.R.C.P.Lond., has been appointed House-Surgeon to the Hartlepools Hospital, vice Paige, M.B., resigned.

MORITZ, SIEGMUND, M.D., M.R.C.P.Lond., has been appointed Assistant Physician to the Manchester Hospital for Consumption and Diseases of the Throat.

OLIVER, M. J., M.B., C.M.Ed., has been appointed Demonstrator of Anatomy in the Medical Department of the Yorkshire College.

PROFFITT, WILLIAM J. W., L.R.C.P.Lond., M.R.C.S., has been appointed Assistant Surgeon to the Burton Infirmary.

REID, IRVINE K., M.D.Aber., has been appointed Medical Officer in the Government Medical Service of British Guiana.

SHAW, HUGH GROSVENOR, M.R.C.S., L.R.C.P., has been appointed House-Surgeon and Visiting Surgeon to the Southport Infirmary, vice J. C. Voight, M.D., resigned.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Assistant Physician.

CUMBERLAND INFIRMARY, Carlisle.—Resident Pupil. Fee, to include board, £20 for six months.

DIOCESE OF NEW WESTMINSTER, British Columbia.—Medical Missionary. Stipend £150, with lodging, and liberty of private practice.

FEMALE LOCK HOSPITAL, Harrow-road, W.—Assistant House-Surgeon. Board and lodging, but no salary.

LEEDS GENERAL INFIRMARY.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing.

NEWCASTLE-ON-TYNE DISPENSARY.—Visiting Medical Assistant. Salary £120 per annum.

PARISH OF DURNESS, Sutherlandshire.—Medical Officer. Guaranteed salary £150, with free house.

PAROCHIAL BOARD OF PENNYGOWN AND TOBOSAY. — Medical Officer. Salary £100 a year.

SALFORD UNION INFIRMARY.—Assistant Medical Officer. Salary £140 per annum, with furnished apartments.

SUNDERLAND INFIRMARY.—House-Physician. Salary £80, rising £10 annually to £100, with board and residence.

WARRINGTON INFIRMARY AND DISPENSARY.—Senior Resident Surgeon Apothecary. Salary £100 per annum, with furnished residence and board.—Junior Resident Surgeon Apothecary. Salary £80 per annum, with furnished residence and board.

Births, Marriages, and Deaths.

BIRTHS.

ARMITAGE.—On May 22nd, at Emu Bay, Tasmania, the wife of Joseph Armitage, M.B.Oxon., M.R.C.S., of a daughter.

COCKELL.—On the 30th ult., at Forest-road, Dalston, the wife of Fredk. B. Cockell, Jun., M.R.C.S., of a son.

GRÜN.—On the 26th ult., the wife of Edward F. Grün, M.R.C.S., of a son.

PAULLEY.—On the 22nd ult., at Pulham Market, Norfolk, the wife of Legge Paulley, L.R.C.P.Ed., M.R.C.S., of a son.

VIVIAN.—On the 1st inst., at Chase Side, Southgate, N., the wife of R. T. Vivian, L.R.C.P.Ed., M.R.C.S., of a son.

WALTER.—On the 28th ult., at Marshfield, Gloucestershire, the wife of W. Ernest Walter, M.R.C.S.Eng., L.S.A., of a daughter.

MARRIAGES.

COWEN—HUXLEY.—On the 27th ult., at St. Michael's, Brixton, George Cowen, M.D., B.Ch., B.A., to Marion, youngest daughter of W. T. Huxley, Esq., of Brixton.

FRASER—RUTTER.—On the 27th ult., at Brixton Independent Church, E. Fraser, M.D., to Helena Blanche Rutter, daughter of D. F. Rutter, of The Limes, St. John's-road, Brixton, S.W.

FRIZELL — EVERETT. — On June 17th, at the Presbyterian Church, Singapore, Thomas Frizell, B.A., M.D., M.Ch., J.P., to Annie, eldest daughter of George Everett, Esq., of Brixton, London.

FURNER—O'REILLY.—On the 28th ult., at the Church of the Sacred Heart, Kilburn, by the Rev. George Bampfield, B.A., assisted by the Rev. Father Cox, O.M., J. Duncan Campbell, younger son of William Campbell Furner, of Salisbury-road, Brighton, and grandson of the late William Furner, J.P., D.L., County Court Judge, to (Minnie) Mary Elizabeth Eleanor, only daughter of the late Michael O'Reilly, M.D., and Mrs. O'Reilly, of Bishop's Stortford, Hertfordshire.

MACKENZIE—FEDDON.—On the 27th ult., at St. Augustine's, Highbury, London, William James MacKenzie, M.B.Glas., to Susannah (Susie), twin daughter of J. Monkhouse Feddon, Esq., of Highbury New-park.

PAINE—SAYERS.—On the 28th ult., at St. Margaret's, Lee, W. H. Paine, L.R.C.P.Lond., M.R.C.S., to Clara Emma, third daughter of W. J. Sayers, of Lewisham, S.E.

STACY—THORN.—On the 27th ult., at St. Philip's, Heigham, Norwich, John Herbert Stacy, L.R.C.P., L.R.C.S., to Naomi Ellen, elder daughter of Charles Thorn, of Norwich.

DEATHS.

DOLMAN.—On the 28th ult., at the Wardwick, Derby, Arthur Henry Dolman, M.R.C.S., L.S.A., in the 57th year of his age.

FERGUS.—On the 29th ult., at Bath-street, Glasgow, Andrew Fergus, M.D., M.R.C.S., Crown Member for Scotland of the General Medical Council, and ex-President of the Faculty of Physicians and Surgeons, Glasgow, aged 65.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

EXAMINATION IN PSYCHOLOGICAL MEDICINE, JULY 25–26, 1887.

PASS EXAMINATION.

(It is not necessary to answer more than four of these questions.)

1. Give the symptoms, bodily and mental, of general paralysis of the insane, distinguishing between the several stages through which it may run. Note the different mental forms which may characterise the invasion of the disorder.
2. With what other diseases may acute delirious mania be confounded? Give the differential diagnosis.
3. What forms of mental disorder may be classed under "alcoholic insanity"?
4. Enumerate the bodily and mental symptoms of mental stupor with melancholia. In what does it differ from mental stupor without melancholia ("primary dementia")?
5. Give the treatment (general and medical) of a case of puerperal mania.
6. In what form and dose would you prescribe hyoscyamine, hyoscine, hydrobromate, urethane, paraldehyde, and hypnone?

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

MEDICAL MEN AND THEIR ACCOUNTS.

SOME patients seem to have a pleasure in writing a grumbling letter to *The Times* instead of promptly paying their medical accounts. The last instance is that of a gentleman who describes himself as a "victim," and complains that he is charged for twelve months' professional medical attendance and medicine £47 9s. He calls the charge "enormous for attendance on one person." It is by no means necessarily so. It may be quite a moderate one. There are no rules in the medical profession which forbid a medical man in general practice to furnish particulars when asked to do so. Indeed, it is proper that he should comply with such a request; but it is unkind to ask him unless the case is very clear. Medical men are always ready to give any reasonable information as to their charges; but to ask them to spend their scanty hours of rest at Christmas in giving long clerical details of attendance is unreasonable.

Mr. T. White.—The method is described in the current (July) number of the journal of the Chemical Society, in an abstract of a paper by L. Spiegel (*Chem. Centr.*, 1887, 363, 364).

Andw. McL.—The qualifications named do not justify the use of the title "Physician."

Juvenis.—The matter shall not be overlooked.

Digitized by Google

HOSPITALS AND HOSPITAL WORK.

THE *Sunday at Home* is publishing an interesting series of papers headed as above, from the pen of Mrs. Brewer. The Westminster is the hospital under notice in the August number of the magazine. The history of the institution dates from the year 1715, when the condition of sick prisoners in London, and of the sick poor generally, excited the sympathy of four gentlemen—Henry Hoare, Robert Witham, Patrick Cockburn, and William Wogan, who, having collected some funds, secured rooms in the house of a lady in Westminster, which formed the nucleus of the future hospital. In 1720 this small band of workers opened an establishment in Petty France, among the very poor of Westminster, where they carried on their benevolent labours for four years, Dr. Colbatch working always gratuitously with them until 1723, when he ceased to belong to them. Soon after a dissension arose among the committee respecting an appropriate site for the institution, the result of which was that the minority separated themselves and founded a hospital at Lanesbro' House, known now as St. George's Hospital, whilst the majority fixed upon a house in James-street. In this building the hospital carried on its work for 100 years, and in 1834 it removed to its present position.

Motor Nerve.—Our correspondent will find the subject fully discussed in any of the standard works on physiology.

Dr. T. Hall Redwood.—The method is described in the *Analyst*, October, 1886, page 197.

A Sufferer should consult a local medical practitioner. We do not prescribe.

Dr. W. Duncan.—The paper has been received, and will appear shortly.

THE BROWN DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to say that in answer to a further appeal I have received the following additional contributions to the above fund. I remain, Sirs, yours faithfully,

USE OF COCAINE IN MINOR SURGERY.

To the Editors of THE LANCET.

SIRS,—Having lately seen several letters in your columns speaking satisfactorily of cocaine as a local anæsthetic, perhaps the following case may be of interest to some of your readers.

A young woman aged thirty came to me a short time ago with a sarcoma of three years' growth from the outer surface of the lower jaw, at a point corresponding to the right molar teeth. I decided to remove it; and as she strongly objected to chloroform, I injected a 4 per cent. solution of the hydrochlorate of cocaine in the neighbourhood of the tumour, and gave the growth itself a thorough soaking with a 20 per cent. solution of the drug. I then removed the tumour, with the result of little or no pain and a rapid recovery without a bad symptom. The tumour was a spindle-celled periosteal sarcoma.

I am, Sirs, yours very truly,

St. David's, Aug. 2nd, 1887. J. GWYTHER HARRIES, L.K.Q.C.P., &c.

THE THERAPEUTICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—By a printer's error the name of Mr. Haward, F.R.C.S. Eng. was substituted for that of Dr. Haward, M.R.C.P.L., F.R.C.S. Eng., in the list of the Council of the Therapeutical Society. Dr. Saundby has asked me to withdraw his name, and Dr. Rayner, M.R.C.P.E., President of the Medico-Psychological Society, has kindly consented to join the Council. I am, Sirs, yours truly,

Longridge-road, W., Aug. 2nd, 1887. A. G. BATEMAN, Hon. Sec.

To the Editors of THE LANCET.

SIRS,—As my name has appeared in the list of the Provisional Council of this Society, will you permit me to announce that I have withdrawn from all connexion with it.—I am, Sirs, yours faithfully,

Birmingham, Aug. 4th, 1887. ROBERT SAUNDBY.

GAELIC MEDICINE.

THE Edinburgh Advocates' Library possesses a valuable collection of Gaelic MSS., many of them embodying such medical science as was professed and practised in the Western Highlands of Scotland between four and five hundred years ago. To one of these the accomplished occupant of the Celtic chair in the University of Edinburgh, Prof. McKinnon, has recently called attention, as having, like its congeners, belonged to the MacBeaths, or Bethunes, or Beatons, who for many generations were physicians of high repute, particularly in the islands of Mull and Islay. Of Irish pedigree, which was equivalent among these islanders to having "come over with the conqueror," these Bethunes were occasionally called in by the Scottish kings, and one of them, "Ferchard Leche" (Farquhar the Healer), cured King Robert II. of a sore and serious illness, for which, as a reward, he was made body physician to His Majesty, and received "the lands of Mollenes and two parts of Hope in Sutherland," as well as the islands lying between Store Head in Assynt and that point of Armadale in Farr. The physician being "himself of kingly descent," doubtless owed to this circumstance the "right royal" character of the "fee." Prof. McKinnon mentions a "Fergus Beaton" as having the following ancient Irish MSS. in the Irish character—to wit, "Avicenna, Averroës, Joannes de Vigo, Bernardus Gordonus, and several volumes of Hippocrates." These documents are in the Advocates' Library Collection, and their subjects are "medical and medico-astrological." They contain a Latin medical treatise, with a translation and commentary in Gaelic. The first chapter is on "fevers—*febris est calor non naturalis*, &c. Then follows a Gaelic paraphrase, with or without explanation." The treatise is divided into chapters, sections, and subsections, in regular scientific order. Further on proverbs and maxims, moral as well as medical, are given in Latin, always accompanied by Gaelic equivalents—e.g., "*quod male incipitur male finitur*," "*per calidum et humidum vivimus*," "*per frigidum et siccum nutrimur*," and so on. A calendar is also given, to which are appended general observations, stating the food and drink appropriate to each month, when it is proper to bathe, when to bleed in the right or in the left arm, what thunderstorms and gales portend, &c. The frequent reference made to the eyesight is curious, and is explained by Prof. McKinnon as indicating diseases of the visual organs due to defective housing and peat-smoke. Impaired eyesight, it may be remarked, is a very common failing in the Irish recruit, often leading to his rejection, at the present day. When a really exhaustive history of medicine comes to be compiled—a work only possible under division of labour,—these Gaelic MSS. will inspire an interesting and instructive chapter.

Enquirer.—We would advise our correspondent not to move further in the matter. He began wrongly by not waiting for the order to examine; and it is only reasonable that the magistrate should wish to consult with the medical man, though the latter is not bound to give him the information. It is necessary to bear in mind that it rests with the magistrate to decide as to the amount of fee to be awarded.

A. K.—The letter was received.

A MEDICAL BIOGRAPHICAL DICTIONARY.

To the Editors of THE LANCET.

SIRS,—It has often occurred to my mind that the important services rendered to our science by various eminent men are deserving of some fuller record than the bare name of the physician or surgeon within brackets, after some description in a text-book. Frequently one is left in doubt as to how much the writer and how much the name in brackets is responsible for. In the Medical Directory we have a record of the professional "men of the time," but of the great men we are yearly losing we are apt, after a time, to have difficulty in finding any detailed account of their labours. Many eminent men escape that "new terror added to death"—a biography; yet I am not singular in wanting to know something of the history and work of the distinguished and disinterested men who have in the past raised our profession to its present place in the very front rank of science. Your own obituary notices supply excellent material for a Biographical Dictionary, and might be considered to obviate the need for a special work, but it is to a limited number that possession of a series of THE LANCET is possible, and to few more that access to it is practicable.

I am, Sirs, yours faithfully,

July 27th, 1887. T. HUME, Surgeon Major.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

Clinical Lecture
ON THE
TREATMENT OF GASTRALGIA.

By SIR JAS. SAWYER, KNT., M.D., F.R.C.P.,
SENIOR PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

GENTLEMEN,—I do not propose to-day to attempt a complete exposition of the nature and cure of gastralgia. I desire to draw your attention to some salient features of practical import in the definition, etiology, symptomatology, and diagnosis of the disorder, and especially to point out to you a means of treatment in which I have found confidence, based upon a long and frequent experience of satisfactory results.

Gastralgia is a very painful affection. The pain has marked characteristics as to position, duration, and onset, and as to its sexual, constitutional, and temperamental associations. The disorder has been variously called gastralgia, cardialgia, and gastrodynia. The nomenclature of the Royal College of Physicians authorises the last name, and it gives "stomach-ache" as a popular synonym. The malady is usually held to be a neurosis, affecting the gastric nerves. According to Dr. Leube gastralgia is limited essentially to the sensitive sphere of the gastric nerves.[1] That the disorder is a neurosis is not quite proven—indeed, it is scarcely demonstrable. But the idea is a good "working hypothesis," which I commend to you. Romberg distinguished two forms of gastralgia: one, which he called gastrodynia neuralgica, he held to be a hyperæsthesia of the gastric branches of the pneumogastric nerves; the other, which he called neuralgia coeliaca, he regarded as a hyperæsthesia of the solar plexus. Although Romberg has indicated what he thought to be the signs and conditions upon which a clinical differentiation of these varieties of gastralgia might be established, I agree with Niemeyer that in a given case it cannot be determined whether the patient's pains occur in pneumogastric or in sympathetic distribution. As Henoch [illegible], although the distinction may rest upon a correct theoretical basis, it is one which is inapplicable and worthless in practice.[2] It has been objected that the term gastralgia is unscientific, because it is only the name of a symptom. In practice, however, and especially in private practice, we meet with many cases for which I know of no other name; and I apply the name to a clearly conceived and clearly defined condition. I call a case one of gastralgia in which pain, deep-seated and paroxysmal, in or about the stomach, of a neuralgic or quasi-neuralgic character, is the leading symptom. But this statement is inseparable from the following important qualification. Pain of the character and position described can only be regarded as that of gastralgia when it is unaccompanied by marked evidences of gastric or gastro-hepatic catarrh, and when, also, it is wholly unaccompanied by physical signs of structural disease either in the stomach or in its neighbourhood. The latter part of this definition involves an essential and a negative conclusion. A negative conclusion, of course, in any case is proverbially difficult. Such a conclusion should only be formed in a supposed case of gastralgia after a complete examination of all the circumstances. Further, a diagnosis of gastralgia should only be held in the conduct of a case of pain in the gastric region as a conclusion which is subject to frequent diagnostic revision; that is, such a diagnosis can only be continued when repeated physical exploration fails to reveal any other, coarser, interpretation of the patient's suffering. I desire to impress this last statement upon you as an important clinical caution, which you must especially remember when your patient is a man at or beyond middle life. In such a person the danger of mistaking a graver and more fatal condition for gastralgia is especially imminent. The diagnosis of gastralgia is one which should never be lightly made, nor negligently maintained. Pain in the gastric region you should always remember, may long appear to be simply gastralgic—that is, independent of any local organic basis,—when the appearance of a tumour, or the discovery of an aneurismal pulsation, or a sudden gastric or intestinal hæmorrhage may prove a diagnosis so comparatively favourable to be tenable no longer.

Romberg's short and vivid description of an attack of the severest gastralgia has been accepted as classical. Let me read it to you. He wrote: "A violent contracting pain at the pit of the stomach supervenes suddenly, or after being preceded by a sense of oppression; it generally extends to the back, there is a sense of fainting, the face is fallen in, the hands and feet cold, and the pulse small, cramped, and intermittent. The pain attains such a pitch as to cause the patient to scream out. The region of the stomach is either swelled and distended like a ball, or, as is more frequently the case, it is drawn in, and the abdominal parietes are tense. It is common to find pulsation at the epigastrium. Pressure is not only well borne, but the patient frequently forces the pit of the stomach against some firm object, or compresses it with his hands. Sympathetic sensations occur in many instances in the thorax, under the sternum, or in the pharyngeal branches of the vagus nerve, while they are seldom met with in the superficial parts." This is Romberg's account of a typical and violent seizure of that form of gastralgia which he called cœliac neuralgia or paroxysmal hyperæsthesia of the solar plexus. You may accept his clinical portrait as accurate, although it is doubtful whether he was correct in localising the pain solely in nerves of the sympathetic system. Under the heading of gastrodynia neuralgica you will find in Romberg's excellent book a faithful clinical description of the milder cases of gastralgia, or "attacks of painful sensations in the stomach," especially as they are manifested in association with the nervous temperament, and with the reflex expressions of sexual irregularities in women. I have ventured from my reading and clinical experience to form the opinion that Romberg did not describe two distinct diseases under the several names of cœliac neuralgia and neuralgic gastrodynia, but merely one and the same affection, which I have been accustomed to call gastralgia, as he met with it in different degrees of severity. Of course a dual interpretation of painful neuralgic affections in the gastric region has an anatomical basis in the dual nerve supply of the stomach—namely, in the innervation of the organ by nerves of the sympathetic system, and also by the vagus. But, truly, in the words of Leube, "in the present state of uncertainty with regard to the mode of action of the gastric nerves, especially with regard to the conditions of sensation, and in view of the anastomotic connexions between the vagus and the sympathetic in the stomach, such a division of cardialgia appears to be both theoretically and practically untenable."

Gastralgia may occur at any age. It is rare at the extremes of life. It is rarer in children than in old people. It is most commonly met with in early middle life. Like all neuralgias, it follows hereditary constitution, and is especially associated with the nervous temperament. I advise you to study temperaments. In them you will find many clues to morbid tendencies. Temperaments denote distinct types of physical form, of habits, and of capacities. A man of nervous temperament is mostly slightly built, and he is generally in a hurry. He is hyper-sensitive to all influences, and to pain amongst them. All his movements are quick, and he has a strong tendency to "fidget" with his ideas or with his extremities. His speech betrays him: he talks volubly, abruptly, and earnestly, often splitting up his phrases, or recalling and correcting them, and especially modifying qualifying words.[3]

As in all neuralgias, women are more liable to gastralgia than men. As, also, in all neuralgias, the manifestation of gastralgia is favoured by every condition which reduces the vigour of a patient's "general health." Gastralgia is a frequent neuralgic development of hysteria; and, in women who are not hysterical, its incidence is often determined by the prostration of anæmia or by the exhaustion which arises from prolonged uterine discharges. In men gastralgia may be a consequence of sexual excesses or of masturbation. All these circumstances must be remembered and dealt with in the causal diagnosis and effective treatment of the disorder.

The diagnosis of gastralgia is not usually difficult. Pain is the leading symptom. When we are satisfied as to the

Digitized by Google

genuineness of pain in the region of the stomach, its correct interpretation largely depends upon an accurate appreciation of various diagnostic data *per viam exclusionis*. I cannot deal exhaustively with this part of the subject to-day. I desire, however, to give you these three cautions, which I have learned in practice: (1) Gastralgia is not a wasting disease. (2) It is not safe to diagnose cancer of the stomach until you can *feel* the cancer. (3) Do not diagnose ulcer of the stomach until you have *seen* blood from the stomach, either in hæmatemesis or melæna. You may take it as a clinical truth, as the late Dr. Wilson Fox clearly insisted, that pain arising in the stomach when the organ is empty, and relieved by the ingestion of food, is almost diagnostic of its nervous origin and nature.[5] Sometimes the pain of ulcer or cancer of the stomach may for a time appear to be relieved by taking food, but such a condition is highly exceptional. There is sometimes a kind of gastric "sinking," even amounting to craving for food, in gastric catarrh, and with greater rarity probably in gastric ulcer; the local discomfort is not, however, relieved by feeding, but, on the contrary, usually made worse. There is another diagnostic sign of great importance in the recognition of gastralgia. It is this: firm pressure over the region of the stomach relieves the local pain. Some patients find this out for themselves, and press a closed hand or the upper rail of a chair strongly against the epigastrium, and so find relief.

My chief object in drawing your attention to the subject of gastralgia is to explain to you a plan of treatment which I have found very successful. I can tell you of a drug which cures gastralgia. Before you prescribe it, however, you ought to find out if there be any prominent pathological concomitants or causal antecedents of the disorder, and deal with them. Anæmia, sexual excess, overwork, work under wrong conditions, uterine discharges, masturbation, &c., must be appropriately met. But for the cure of the gastralgia something more is usually necessary. Of all the directly therapeutic results in medicine with which I am acquainted, one of the most demonstrable is that which can be produced by the suitable exhibition of arsenious acid in uncomplicated gastralgia. I give one-twenty-fourth of a grain of arsenious acid, made into a pill with two grains of extract of gentian, thrice daily, between meals. The use of this remedy must be continued for a few weeks. In a case of moderate severity no other medicinal treatment is necessary. The gastralgic pains become less frequent and less severe, and recovery is steadily and surely attained. In severer cases I use some form of counter-irritation to the epigastrium, and I usually employ a rubefacient liniment of ammonia. In the severest cases vesication by a fly-blister is of service, and the blistered surface should be kept raw for some days by means of a daily dressing of savin ointment. But you must not rely upon treatment by drugs alone. Every hygienic adjuvant which tends to raise the strength of the patient is of high value in the cure of gastralgia. I especially advise you to make sure the sufferer feeds well and fully. The diet should be generous. A "dyspeptic" regimen makes a case of gastralgia worse. When you are satisfied there is no, or but slight, gastric catarrh in the gastralgia of a fairly vigorous adult, you should direct a dietary after this plan:—Breakfast: bread-and-butter or dry toast, with some fresh white fish, or some cold chicken or game, or a mutton chop, with a breakfastcupful of cocoa or weak tea or coffee. Dinner (1 P.M.): fresh beef or mutton, with bread, potatoes, cooked green vegetables, a fruit tart or a farinaceous pudding, with a glass of light bitter ale. Tea (at 5 P.M.): bread-and-butter or dry toast, with a small cupful of cocoa, tea, or milk-and-water. Supper (not later than 9 P.M.): white fish, or some cold chicken or game, or a little cold meat, with bread, and a glass of ale.

[5] Reynolds' System of Medicine.

TAUNTON AND SOMERSET HOSPITAL.—At a recent special meeting of the governors of this institution, called with reference to the gift of £5000 by an anonymous donor towards the jubilee extension fund, it was resolved that £800 should be paid for the site of the proposed nursing institute, and as this property belonged to the hospital, the sum will be paid into the general fund. The remainder of the money, after paying for this building, the children's ward, and the out-patient's department, will be invested as an endowment for the support of the nursing institute. It was stated that the fund amounted to £10,489.

ABSTRACT OF THE

Address in Public Medicine

Delivered at the meeting of the British Medical Association at Dublin,

BY THE REV. SAMUEL HAUGHTON, M.D.,
SENIOR FELLOW, TRINITY COLLEGE, DUBLIN.

AFTER welcoming the members of the Association to Dublin, Dr. Haughton said that the natural rights of every human being born into the world might be shortly summed up as follows: liberty, air, water, food, heat, and light. The most important of these were air, water, and food. Without air, we live three minutes; without water, we live three days; without food, we live three weeks. Instincts stronger than reason compel us from our birth to seek these natural rights for ourselves; by force, if necessary; our progress has, however, been slow in recognising the equal claims of others to the enjoyment of these natural rights. In 1851 the window tax was abolished, after having deprived millions of their fair share of sunlight and air for more than one hundred and fifty years. In principle, this was as monstrous a tax as that levied upon urine by the Roman Emperor, Vespasian.[1] The supply of pure water to the poorer classes was as defective as that of sunlight and air. In 1836, the first year of complete registration, the water supply of London was 36 million gallons daily, much of which was drawn from the tidal portion of the River Thames, more or less imperfectly filtered; but owing to the doubtful purity of the water supply, many persons preferred for drinking purposes the water derived from surface pumps, some of which were in the immediate vicinity of churchyards. In 1845 the water supply of London had increased to 45 million gallons daily; in 1858 it was 75 million gallons; in 1886 the supply reached 180 million gallons daily. In the good old times Ireland was not much better off. The City of Waterford depended chiefly for water supply upon its own surface wells. One of these, which appears to have been in great demand, was analysed by Sir Charles Cameron, who declares it to have been, without exception, the worst water he had ever met or read of. On closely smelling this water, a faint urinous odour was perceptible, and the amount of ammonia contained in it exceeded the quantity he had found in some specimens of Dublin sewage.

Discussing the death-rate and density of population, Dr. Haughton observed that the death-rate of a population was the number of deaths for 1000 living persons of all ages in a year. The density of a population was the number of persons residing in a square mile. It is well known that after the density of population exceeds a certain limit the death-rate begins to increase, so that the density of population must be regarded as one of the causes of death-rate, though only a secondary cause. The first person who attempted to reduce the relation between density and death-rate to a mathematical form was the late Dr. Farr, who rendered such important services to the science of vital statistics. He selected seven groups of districts of England and Wales arranged according to density of population, and compared their death-rates; from these data he derived the following formula:—

$$m' = m \left(\frac{D}{D'}\right)^{0\cdot11998}$$

where m, m' are the death-rates of any two places, and D, D' the densities of population at the same two places. This is equivalent to assuming that the relation between density and death-rate may be represented by a parabolic curve, of the form[2] $Y^n = px$. Dr. Farr assumed that n and p are constant, and from this assumption derived his formula, in which, however, the column of differences is too large, and gives the large probable error $\epsilon = +$ or $- 3\cdot11$ in the death-rates. If we assume that the values of n and p vary at different parts of the parabolic curve, we can readily find formulæ for calculating, in which the probable error is

[1] ——— Iucri bonus est odor ex re
Qualibet ———

[2] This form of parabolic curve represents also in meteorology the relation between radiation and temperature.

Digitized by Google

reduced to less than one-third of that of Dr. Farr's formula. The values of n which he employed are—

$n = 0{\cdot}118$ between 19 and 25 death-rates.
$n = 0{\cdot}135$ „ 25 and 32 „
$n = 0{\cdot}105$ „ 32 and 40 „

By using these values we find that the column of differences gives the mean probable error $e = +$ or $- 0{\cdot}97$ which is less than one-third of the mean error of Dr. Farr's table. For the use of persons not familiar with mathematical tables Dr. Haughton has constructed the following table of death-rates calculated from densities, the use of which is obvious.

Death-rate.	Density.	Death-rate.	Density.
15	146	28	4,332
16	156	29	5,580
17	165	30	7,140
18	175	31	9,051
19	186	32	13,480
20	287	33	18,059
21	434	34	23,615
22	645	35	31,673
23	939	36	41,371
24	1,347	37	53,665
25	1,804	38	69,293
26	2,527	39	88,648
27	3,324	40	112,990

This table enables us to determine the average death-rate when we know the density of a population, but the actual mortality depends on other causes, which vary from place to place. In order to make full use of it, we must form a standard of perfect health. Dr. Farr selected for this purpose sixty-four localities in England and Wales where the mortality of the people ranged on an average from 15 to 17 per 1000, and fluctuated only slightly from year to year. The inhabitants are 973,070, living on 4,797,315 acres. This gives a density of 3155 to the square mile. From the preceding table the mortality of the whole population of England and Wales at that density would be 26·21, so that in these healthy districts upwards of 10 lives per 1000 are yearly saved by the absence of causes which injuriously affect the other parts of the country, and this happy million of country folk have 10,000 fewer funerals to attend each year than any other million in the community. The inhabitants of this Arcadia follow agricultural pursuits, are scattered thinly over an open country, often on high ground, so that the impurities which they produce are dispersed and diluted in the air and water. They do not breathe each other's breath in theatres and churches; they do not drink water sullied by impurities; they do not drink poison in gin palaces; their minds are not overwrought by dissipation, passion, or intellectual effort; yet, in Dr. Haughton's opinion, they purchase their low death-rate at a great cost. The value of life does not depend on its mere length; it depends on the number and value of the thoughts of the liver. These people do not live, they only vegetate; they are in happy ignorance of Greek and Latin, and have never heard of Swift and Pope, of Molière and Voltaire, of Shakespeare and of Newton. They are a dull race, and he should prefer living among a livelier people, where he could live and take his chance of a share in the 10,000 additional funeral feasts and baked meats. Comparing the calculated with the actual death-rates of London, Edinburgh, and Dublin, Dr. Haughton pointed out that in all three cities the former exceeded the actual death-rate, showing that all the cities have a death-rate less than the average, and the column of differences indicates the total effect of the sanitary causes acting in favour of each city—viz.:

London	13·89
Edinburgh	15·55
Dublin	4·02

Thus the sanitary causes acting in favour of Edinburgh and London were nearly four times as great as those in Dublin. Setting aside the absence of epidemic disease, these causes are—air, water, food, clothing, lodging, and drainage.

With respect to water Dublin is better off than most other towns, but large districts of Dublin are very badly provided with fresh air and good lodging, owing to the continued existence of overcrowded tenement houses; and he could testify himself, from personal observation extending over forty years, that in winter time large numbers of children suffer severely from the want of good food and fuel. With regard to the drainage of Dublin it is admittedly bad.

Dr. Haughton said that he had on a former occasion expressed the opinion, and given his reasons for it, that Dublin is unfavourably situated, as compared with other towns, with respect to drainage. If this be so, it ought to be a strong incentive to its inhabitants and local authorities to combine all their resources and intelligence to devise a scheme of main drainage, which would possess all the well-known medical qualities of the perfect cure, by acting *cito, tute, jucunde*. For every 1000 men, women, and children living in the ill-drained and overcrowded liberties and slums of Dublin, five more must die each year than die among 1000 of the inhabitants of the suburbs of Dublin.

He had seen cholera in 1866 and small-pox in 1871 leave their congenial haunts amid the dwellings of the Dublin poor, and carry terror and death into the homes of the rich. And at such times the fever hospitals received hundreds instead of tens of pounds, and thousands instead of hundreds—offerings to the fetish of Pestilence, of as little value as the large sums cast into the temple treasury at Jerusalem, because they were wrung from the pockets of the rich by a terror as abject as their former selfishness was mean.

From tables of the death-rate of Dublin, which he quoted, Dr. Haughton said that the following inferences may be fairly drawn from the foregoing figures;—1. That the death-rate of both city and suburbs is greater than it ought to be. 2. That during the last five years, in which the Corporation of Dublin have spent much money on street sewers, paving of streets, domestic scavenging, and clearing of unhealthy areas, a saving of life amounting to 3 in 1000 a year has been effected, and nearly 4000 lives saved from death during that time. 3. That the death-rate of the township population has remained stationary during the whole fifteen years. The results of the expenditure on sanitary improvements may appear small, but they are only the beginning of a better state of things, and he had no doubt that the improvement would proceed at an accelerated pace, like a stone rolling down a hill: *vires acquirit eundo*, every thousand pounds spent on sanitary work enabled the next thousand pounds to do more work and cause a greater amount of benefit.

Dr. Haughton concluded by quoting tables showing that the death-rate is nearly in the inverse ratio of temperature.

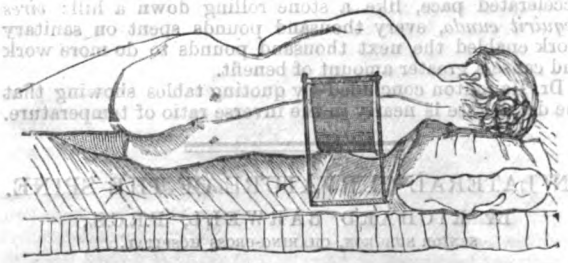
ON LATERAL CURVATURE OF THE SPINE.

BY RICHARD BARWELL, F.R.C.S.,
SENIOR SURGEON, CHARING-CROSS HOSPITAL.

IV.

THE considerable osseous changes described in my last paper[1] originate, as I have shown, in certain bad postures of the trunk, forced on it either by pelvic obliquity by certain occupations or habits, in either case persisting for months and years. Hence stand out in still stronger light the importance of early detection and treatment. The slow progress of such defect of growth can only be met by a gradual method of cure, which, like the disease itself, must be persistent, therefore must not be violent or of a kind which by weight and rigidity of appliance, by restraint of natural movements, injuriously affects the health. Yet the treatment must be real. Mere posturing and calisthenics alone do no more, and can do no more, than prevent a tendency to crooked spine—in other words, they are by themselves powerless to cure a lateral curvature, though they may avert one which as yet is only threatened.

The treatment which I advocate is one that *leads* the spine aright rather than *forces* it into this or that attitude. It consists in one part of substituting for the muscular acts, which produce deformity such as tend to restore symmetry, and in another part of counteracting by elastic and yielding power the lateral deviation as well as the morbid twist. The former devices, which I term "adjuvants," therefore naturally fall into two classes—those that act against the curve, and those that are directed against rotation. For an account of the first class I must refer to what has been said in my previous papers concerning pelvic obliquity and its influence on the spine, more especially to Figs. 1, 2, and 3,[2]



[1] THE LANCET, July 23rd. [2] Ibid., June 25th and July 9th.

Digitized by Google

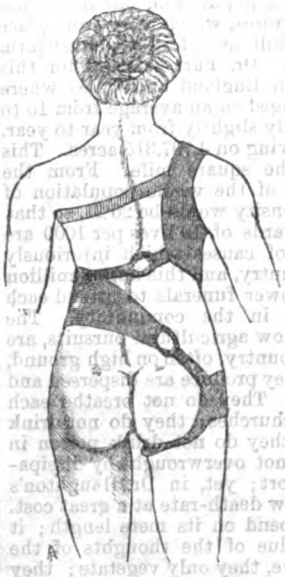
which show that its effect does not stop at the loins, but is continued up into the dorsal region. Advantage may therefore be taken of an artificial obliquity by means of the *sloping seat* (Fig. 4), and in some cases by some additional thickness to the heel of the left boot. If the patient ride, she must do so on the wrong side of the horse—i.e., with the left leg in the pommel.[3] The *loop girth*[4] is also a valuable appliance for those cases in which the lumbar curve is somewhat strongly marked. The *lateral swing* (see Fig. 6) is directed against both deviation and rotation; its method of use for lumbar curvature has been already described. For dorsal curve it must be placed somewhat higher on the figure, as in Fig. 8. The patient uses it, of course in her customary nightdress, for about twenty minutes night and morning at the commencement of treatment, the period being gradually increased. She must lie in it, not completely on the right side, but a little turned over on the back, by which means the weight of the body acts both against lateral deviation and rotation.

The adjuvants aimed at the counteraction of rotation require some explanation. One of the agents, if not the chief one in turning the upper on the lower part of the trunk, is the serratus magnus, which may be regarded in conjunction with the rhomboids as a fleshy mass inserted into the nine upper ribs, whose mode of attachment to the spine indicates the lever-like use to which the muscle puts them in turning each vertebra; in this point of view the posterior costa of the scapula is to be regarded as a mere intersection. Thus it is evident that any position of shoulder which decreases the distance between that edge of bone and the insertion of the serratus diminishes on that side the backward pull of the muscle on the ribs, while postures which augment that distance add to that action on those bones. As the serratus is a powerful respiratory muscle, and also is one of those that

FIG. 8.

supports the scapula in its position and upholds a great part of the weight of the shoulder, we can take advantage of these functions, thus: the patient is to acquire the habit of keeping the left forearm behind the waist—a not ungraceful posture, which may be assumed at any time and in any place. A more potent aid, but which can be only periodically practised, is what I have called the *respiratory exercise*. In each of two walls facing each other a staple is fixed, from which cords, rendered elastic by the intercalation of accumulators, pass to the neighbourhood of a chair midway between the walls. On the chair is placed the wedge-shaped cushion, on which the patient sits, high side to left. She then crosses her right arm in front, her left arm behind the body, grasping in each hand the cord, which must be at a tension of at least 2 lb., and which is provided with a suitable handle. Thus placed, she takes long, slow, and deep breaths; about twelve is sufficient in the beginning, afterwards the number may be considerably increased.[5] Another device, valuable for slight rotation by itself, or as an addition to the other means for severer cases, is to weight the left arm. This is done by a strip of lead one-eighth of an inch thick, three-quarters of an inch broad, and ten or eleven inches long, weighing about four ounces; it is covered with thin mackintosh and a silk ribbon somewhat longer than the metal, so that it may be tied on the arm about the insertion of the deltoid. I am often asked if my patient is to lie several hours a day on the back. This is the remains of an antiquated mistake; and many a girl has been condemned to very serious loss of health by continuous and long-continued recumbency. Lying on the back, although in that attitude the spine is of course straighter than when it supports the weight of the body, has no curative effect whatever; if too much practised it only weakens the muscles, so that when the patient gets erect the spine only yields more to the superincumbent load. Therefore my answer to the question is to let her lie down as soon as she feels fatigued, and after any exercise, even though unconscious of fatigue, for about half an hour. Quite young people, healthy and strong save for the commencing curve, often say they never feel the back tired; nevertheless, it is well to relieve the erector spinæ from work for a considerable part of the day—for instance, while reading or learning tasks by rote—occupations that harmonise badly with the supine position. I tell them, therefore, to do all this sort of work while lying on the front of the body; and to this I add that the right arm is to lie by the side or under the chest, while the left elbow is placed on the couch and the head reposes on the left hand, thus again throwing work on the serratus of that side. Some complain that lying in this way caused pain in the loins, because this part is hyper-extended; that may be entirely obviated by putting a rather thick pillow under the body, about the level of the umbilicus. It must be understood that these aids are not all used simultaneously in any one case, nor in many are they all used throughout its management; the influence of nearly all of them is at any given moment

FIG. 9.



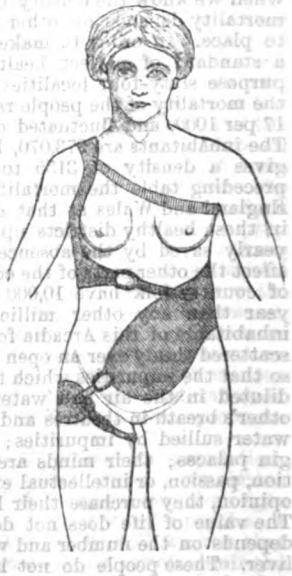


FIG. 10.

slight, but the cumulative effect of persistent use is very considerable.

More important, probably, are certain mechanisms to be explained immediately. I have already stated that "although in all cases of scoliosis the vertebra which has deviated most is also that which is most rotated; yet curvature and rotation do not in different cases bear the same proportion to each other." Hence a very important difference in the direction of the power to be applied to the spine. Let us first suppose a case in which lateral deviation is the chief factor, the patient standing upright with her back to the surgeon. Most certainly, especially if not in the frequent habit of making these examinations, he will put his hands at the patient's sides opposite the chief point of dorsal and of lumbar convexity, and then, by pressing them in opposite directions, will endeavour to find how much force is required to straighten the spine, which he will succeed partially or entirely in doing. The bandage called *dorso-lumbar* effects permanently what those hands do temporarily—pressing, that is to say, each convexity towards the middle (straight) line. (See Figs. 9 and 10.) It is constructed by adding to the loin bandage already described[6] a dorsal piece made of the same material; its shape is shown in the figure. The two straps provided with rings that pass across the body, back and front, from the lower corners of the dorsal piece, are the active forces; the little strap higher up, shown in lighter

[3] Throughout this description of treatment a curvature, convex to the right in the dorsal, to the left in the lumbar region, is assumed.

[4] Ibid., July 9th.

[5] I need hardly point out how in this position the action of the serratus on the ribs is minimised on the right and augmented on the left side.

[6] THE LANCET, July 9th.

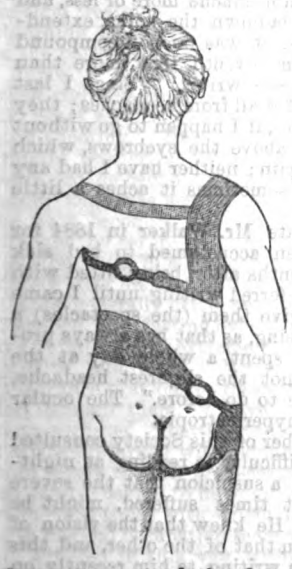
colour, is inch-wide elastic webbing (haberdasher's flat elastic); it merely guarantees the upper part of the dorsal piece from slipping. The power of this appliance acts in the direction of the radii of the curves, that which has the most mechanical advantage; yet being elastic, it in no way hinders healthy exercise, is by no means uncomfortable, but the reverse, and can be worn imperceptibly under the patient's daily dress.

The *rotation bandage*, which at first glance looks almost identical, has a very different action, and is to be employed when rotation is strongly marked. When both deformations are pretty severe, it is better to begin with that just described and at the proper time, difficult to define in writing, substituting the rotation belt. The alteration can be carried out by the bandagist in a couple of hours, for it has the same shaped loin and shoulder piece; but the straps—i.e., the forces—act differently. The only point of connexion between the loin and dorsal part is the strap running across the front of the body (Fig. 12), the "front cross strap." From the back, upper, and lower corners of the dorsal piece a webbing loop encircles the left upper part of the chest and shoulder; it is, of course, rendered elastic, and is provided with means of adjustment. In putting it on, when the dorsal piece is in place, the loop is first arranged with a proper degree of tension, and then, also with appropriate tenseness, the front cross strap is adjusted. As this is done

FIG. 11.



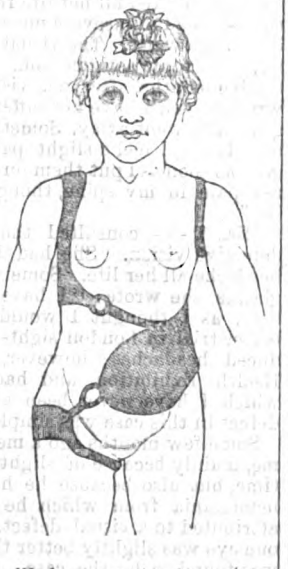


FIG. 12.

the upper part of the figure will be seen to turn (see Figs. 11 and 12) and to respond to every little additional tension of the front cross strap by an increased untwisting of the spine. Moreover the rings, both of the front cross strap and of the loop, play with every inspiration thus in a way that is easily understood, but too long to explain, every breath is a little step towards rectification of rotation. I devised this form of belt about two years and a half ago, and find that many cases such as previously I could only benefit are quite amenable to this treatment.

The prognosis of spinal curvature depends partly on the age of the patient, partly on its severity, and partly on its cause. Thus, scoliosis from severe rickets or from solidification of one lung is not to be cured—merely benefited. Lumbar curvature, arising from inequality of growth in a lower limb (pelvic obliquity), not the result of disease (morbus coxæ, infantile paralysis, &c.), is quite curable; indeed, if taken early, the management is preventive rather than curative. Such inequality nearly always corrects itself at due age, the limb which grew quickest ceasing to grow first; we have only to prevent the resulting lateral deviation becoming fixed. There is a certain senile dorsal curvature which is incurable; it is connected with a peculiar atrophy of the bones, and is not the subject of my paper. All other forms not depending on lung disease are curable in the first and second stage, and may be greatly benefited, even in the first part of the third, provided the patient be not too old—say over thirty. The treatment and alleviation of severe curves in persons somewhat advanced in years cannot be here described.

ON HEADACHE, DUE TO ERRORS OF THE REFRACTIVE MEDIA OF THE EYE.[1]

BY T. H. BICKERTON.

GENTLEMEN,—It is not my intention, in this short communication, to dilate upon the subject of headache in general—this would, indeed, be beyond my province; but I wish to draw attention to a cause of headache which, though it of late years has attracted some notice, is still but little recognised, and does not appear to receive by any means that attention which it deserves.

The cause of headache that I would wish to bring prominently forward is this: (1) That disorders of the refractive apparatus of the eye will give rise to headache; and (2) that the headache produced by these disorders may vary from the slightest, such as are barely noticeable to the most intense, in which the head pain is so great as to suggest the possibility of actual disease of the brain. If it can once be proved that headache may be caused by errors of refraction and other equivalent complaints of the eye, then, seeing what a large proportion of our population are affected by these errors, it would not be unwise to discount this factor in every case of headache, for which there is no definite cause before we seek for another. To oculists, and to those medical men who believe that ocular trouble is a cause of headache, the above statement may appear unnecessary; but anyone looking through the vast amount of literature written on the subject of headache will be struck by the fact that there are few of the eminent men who so wrote who recognised the eye as even a possible cause of the troubles which they have described with so much exactness. Where the eye is mentioned, it is to describe some special sensations referred to this organ, which sensations are considered to be symptoms of the complaint. That I am correct in my statement may be seen by a reference to Bristowe's "Medicine," to Quain's "Dictionary of Medicine," to "Headache, its Natural Causes and Treatment," by Dr. Day, to Reynolds's "System," or to Ziemssen's "Cyclopœdia of Medicine," for in not one of the works mentioned will there be found a single line which would suggest refractive errors of the eye as a possible cause. Ziemssen, after having mentioned the known causes of headache, goes on to say (vol. xi., p. 137): "A large group of cases still remain in which no anatomical causes of the pain can be shown to exist, and in which we seem compelled to admit the presence of abnormal conditions of excitation of sensory nerves ramifying on or in the head; these are the cases which may with some propriety be included under the head of 'nervous headache.'" Again, he says, "To what special locality, however, we should refer these nervous headaches is still unsettled, and we can only offer guesses at the truth"; and still further he makes the remark that "we not unfrequently meet with very puzzling cases in which literally no cause can be discovered." The fact therefore—if it is a fact—is not generally known to the profession, and all absence of notice of it in these standard works on medicine shows that it had not occurred to physicians to look to defects of the eye to explain headaches whose cause was obscure. My argument is that in similar obscure cases, where all the known causes of headache have been eliminated, it will be found that a large number of these headaches are due to some error of refraction of one or other eye, or of both.

That there is a direct connexion between a refractive error and headache and nervous symptoms was first publicly demonstrated, I believe—or, at any rate, the attention of the profession was first specially attracted to the connexion,—by the now historical case which was related by Mr. Brudenell Carter to the Clinical Society of London in the session 1874-75, and since incorporated in his work on "Diseases of the Eye" (p. 564). In his case a young gentleman studying for honours at Oxford was mysteriously attacked by head symptoms of much severity. These symptoms were attributed by the Oxford practitioner, by his home medical man, and by the eminent London physician whom he consulted, to some affection of the brain. On their recommendation he left Oxford, and took a voyage to Australia, but, returning no better, he was advised to abandon the idea of succeeding to his father's

[1] Read at the Liverpool Medical Association, Nov. 25th, 1886.

Digitized by Google

large commercial business, and to also break off a marriage engagement he had made when in health. He was taken to Mr. Carter by his father, "with the statement that he had some obscure and intractable brain disease, and with a request that he would make an ophthalmoscopic examination in order to see whether it could throw any light upon the state of the cerebral circulation." Mr. Carter found him to be myopic and ordered glasses. Three weeks afterwards his patient was well, and two years after this he had "the satisfaction of hearing that the cure was permanent."

Since that time there have been other writers, both in this country and abroad, who have called attention to the same subject, and amongst many may be mentioned the names of Brailey, Higgens, Lauder Brunton, Hewetson, and Weir Mitchell, and the result of their observations bids fair to revolutionise the opinions held respecting the causes of headache, and to simplify in many cases, and to an extent undreamt of, one of the most troublesome complaints to which flesh is heir. My belief, and it is a belief which becomes more and more strengthened each day, is that a large number of headaches are due to faulty conditions of the eyes, and in order to support this statement I will venture to bring under your notice a number of the cases which have led me to this belief. I have gone carefully through the first thousand cases of refractive errors which have been under my care since my attention was drawn to this question, and I find that in 277 of these headache was a distinct symptom. I do not say that the headache occurring in each case was at all comparable; in some cases it was but slight and was only felt at intervals, in others it was of the utmost intensity and constant, and in many it was associated with marked nervous symptoms. One point that I would call special attention to is that, except where sent by medical men, not one of the individuals suffering from headache came on that account. They came because of defective vision, and the history of headache was only elicited by inquiry. The following are the cases I refer to.

Mr. R. C. H——, aged thirty-seven, consulted the late Mr. Shadford Walker in the year 1882 on account of dimness of vision. He had never had good sight, and although he had on many occasions tried to get suitable glasses, he had not been able to find any that were of much use to him. Of late years he found his sight "weaker," being unable to read or write for more than a few moments together, a persistence in reading making him feel dull and sleepy. For years he had suffered from headache, and periodically accompanying these headaches were bilious attacks of much severity. During these attacks his sight used to go altogether. This gentleman did not associate his headaches and bilious attacks with his eyes, though he was well aware his vision was not good. The special error of refraction in this case was one of compound myopic astigmatism. Glasses were ordered, and from that time not only has his vision been very greatly improved—he being now able to read all day with ease and comfort,—but his headaches and bilious attacks have entirely disappeared.

Miss J. E——, aged forty-two, companion to a lady, and having to do a great deal of reading and sewing, consulted the late Mr. Shadford Walker in July, 1881, for defective vision. Some eight or nine years ago after prolonged reading for some hours she became dizzy and fell down. Throughout the whole of her life she has suffered from what the doctors have called "bad bilious attacks." These consisted in severe aching and throbbing pain in the head, especially at the top and across the forehead, and in a sickening feeling in the stomach. For some time past the headache has been constant, being felt from the time she awakes in the morning until she goes to sleep at night. For some years she has worn glasses which she had picked up from an optician, and which she now finds are but of little use to her. Since the glasses—which corrected the high compound hypermetropic astigmatism existing in each eye—were ordered for her, now more than five years ago, this lady's head symptoms and bilious attacks have entirely disappeared, and she is able to fulfil her duties to her mistress and to herself with entire satisfaction.

Mrs. R——, aged thirty-one, consulted the late Mr. Shadford Walker in 1884, because a few months earlier she had accidentally discovered that the vision of the left eye was not so good as that of the right. The history she gave was that for the last eight or ten years she had suffered from headache; during the last five very severely. Attacks of severe neuralgic headache would come on apparently without cause, which blinded her and rendered her prostrate; and these attacks only passed off after a night's rest. Her condition was one of compound hypermetropic astigmatism. Correct lenses were ordered her, and six months after she writes thus: "I am glad to be able to tell you that I have never suffered from one really severe headache since wearing the glasses you ordered. I wear them entirely in the house, as it is less trouble than having to constantly put them on when reading, writing, &c. If by chance I go to a concert, or pay calls, or go shopping, without my pince-nez, I am almost certain to have a slight attack of the headache or pain in the right eyeball, and which only comes on after being without the glasses for some time. I have not been in town since August, or would have called to tell you how pleased I am to be rid of those violent headaches."

Mrs. B——, aged thirty-eight, the wife of a clergyman, and having to do a large amount of her husband's writing, consulted the late Mr. Shadford Walker in 1884 because of defective sight. She had suffered from daily frontal headache as long as she could remember, at times being prostrated with it. Her ocular defect was simple myopic astigmatism. In a letter written six months after being fitted with glasses she says: "The glasses have been such a success that I cannot help feeling they ought to be still more so. Owing to their use I am thankful to say my headache has entirely disappeared."

Miss S. A. E——, aged twenty-three, sought advice in Oct. 1885, because of aching of her eyes after near work for the previous six months. On inquiry, it was found that she had suffered all her life from headache more or less, and that she had also severe neuralgia down the spine, extending to the waist. The visual defect was one of compound hypermetropic astigmatism. On Nov. 6th, 1886, more than twelve months after her visit, she writes: "Since I last wrote to you I have not suffered at all from headaches; they gradually went away. Sometimes, if I happen to go without my glasses, I feel a slight pain above the eyebrows, which goes as soon as I put them on again; neither have I had any real pain in my spine, though sometimes it aches a little bit."

Miss T—— consulted the late Mr. Walker in 1884 for defective vision. She had been accustomed to bad sick headache all her life. Some months after, being fitted with glasses, she wrote: "I have deferred writing until I came here, as I thought I would give them (the spectacles) a better trial in London sight-seeing, as that has always produced headaches; however, I spent a whole day at the Health Exhibition, and had not the slightest headache, which I have never been able to do before." The ocular defect in this case was simple hypermetropia.

Some few months ago a member of this Society consulted me, mainly because of slight difficulty in reading at night-time, but also because he had a suspicion that the severe hemicrania from which he at times suffered, might be attributed to a visual defect. He knew that the vision of one eye was slightly better than that of the other, and this was found to be the case. On writing to him recently on the subject, he wrote to say: "Since I have worn the glasses you ordered me my headaches have greatly diminished in force and frequency."

A case which has been one of great interest to me is the following. In the spring of 1883 a lady consulted Mr. Walker on account of short sight. She was married, thirty-eight years of age, and what at once attracted attention was the perfect whiteness of her hair. For the previous nine years she had suffered from almost constant severe frontal pain and parietal headaches, and to these she attributed the whiteness of her hair. Her letter, dated the 7th of this month, more than three years after her first visit, will explain itself: "In answer to your inquiries about my headache, I can truly say that since I was examined by Dr. Walker and yourself I have suffered less and less from the violent pain I was so frequently prostrated by. This is due, no doubt, partly to the use of glasses and partly to improved digestion, and also gradually the intense internal inflammation and irritation have been overcome, and I am now so much stronger in consequence that I can live a more rational and active life. I hope you will understand that I consider you very greatly helped me to freedom from headaches, but I feel sure glasses alone would not have cured them all. One has headaches from so many causes, and I had so much pain to bear, and was in such an unnerved condition, that I seldom passed many hours consecutively without headaches of one kind or another. I sometimes now feel the old strained feeling in one eye, and then follows a headache, but

Digitized by Google

I avoid trying my sight as much as possible, and try to be content not to be able to see, instead of forcing my eyes as I used to do."

A somewhat similar statement to the one above is made by a lady, a teacher, who came concerning her sight in 1883, who also stated that she had suffered from headache all her life, and that the medical gentleman to whom she went before consulting the late Mr. Walker had greatly alarmed her by saying she was suffering from brain disease. In her letter of November 7th, 1886, occurs this paragraph: "My headaches have greatly diminished since I began the use of glasses, though I can scarcely think the glasses alone can have caused the improvement, as my headaches date from early life."

Both these cases are especially interesting, inasmuch as both admit that the headaches they suffered from have been greatly diminished by the use of glasses; but both also attribute the diminution to other causes as well. The one cannot believe that the glasses alone have caused the diminution, "because her headaches date from early life," but she evidently forgets the fact that she has had the possession of her eyes all her life also; and the other believes that the improvement in the general health is a main cause. Granted; but what is it that has caused that improvement? I have a strong opinion that the use of the glasses, by relieving the almost constant and severe headache, has had a great deal to do in permitting the improvements of the general health, if for no other reason than that the eminent medical treatment which she had undergone previously to obtaining glasses had been followed by a continued decline in the patient's health.

James P ——, aged thirty-one, joined the English army when eighteen years of age, and was discharged after nearly six years' service, because, as he says, "he could not make good shooting." He then took to the occupation of a lithographic printer, at which he has continued since. Five years ago he began to suffer from simple headache, which before long was accompanied by pain across the forehead, the pain becoming shortly after very acute. He next was attacked by severe bilious and sick headaches, and he thus describes them in a statement which he wrote for me immediately after his first visit to me. It runs as follows: "These attacks generally came on in my leisure time on Saturday afternoon, and, lasting over Sunday, accompanied by excessive vomiting and extreme prostration, also deprived me of appetite and sleep. My eyes always bore a bloodshot appearance previous to these attacks, with a burning sensation through them. I have taken many remedies, but all to no purpose. They allayed the pain for a short time, but it always returned with redoubled force. Every attack was more severe than its predecessor. This continuation of pain has lately begun to have an effect upon my mind, being troubled at times with suicidal intentions, and making my daily life and occupation seem a burden to me." But he had not suffered in this way without seekin g relief. He tells me that he has seen, in America and in this country, between ten and fifteen medical men. To one gentleman in New York, who had made a specialty of headache, he paid the sum of five guineas, and for this moderate fee he received an examination lasting for more than an hour and a half, and some purgative pills. Coming over to England and settling in Liverpool, he applied, as a last resource, to the Royal Infirmary, and having told his tale to Dr. Davidson, that gentleman informed him that his troubles were most probably due to his eyes, and kindly sent him on to me. An examination showed his ocular defect to be one of high compound hypermetropic astigmatism, and this was without much difficulty corrected by glasses. Almost from the day on which he began to wear his glasses his troubles began to diminish in frequency and in intensity, and they have now almost ceased. He says he is a different creature, able to do his work with ease and comfort and with satisfaction to his employer, which formerly had not been the case, and able to take a pleasure in life which had long been unknown to him. This man had known for many years that his vision was defective, yet he had never associated this defect with his troubles, nor until he met Dr. Davidson had the question of his vision been put before him.

In a case which was sent to me some little time ago by Dr. Cranstoun Dale, the following history was given by the lady herself: "I have suffered from headache for twenty-five years, the pain being chiefly across the forehead and top of the head. For the last eighteen months the pain has been almost constant, and is sometimes so bad that I have to lie down and have a bandage tied tightly round my head. I have never gone to bed for eighteen months without having a bandage round the head. At times the pain is intense—my brain feels on fire, and my head seems as if it was opening and shutting. My vision for distance is very good, but as soon as I do any near work my eyes burn and prick and the headache comes on. It has never occurred to me that my eyes and my headaches are connected, but Dr. Grimsdale tells me that very probably it is so." This lady had simple and unequal hypermetropia, and since being accurately fitted with correcting lenses her troubles have steadily diminished.

A similar case to this was that of a hospital nurse, sent to me on account of severe headache by Dr. Cameron, and in this case also the constant use of glasses has been followed by complete relief.

These, then, are the cases (the relation of which I trust has not been wearisome) which I have selected out of a number of very similar ones, which have come under my notice, and which have led me to attach an importance second to none to the great influence which errors of the refractive media of the eye have in the production of headache. When one sees, as I have seen, headache from the simplest to the more intense, headache intermittent or constant, in some cases associated with indigestion, biliousness, and vomiting, in some with giddiness and faintness, and in others with languor, sleeplessness, and general debility; when one sees not only the headache but all its varied concomitants vanish by the means of accurately fitted glasses—then I say it is impossible to come to any other conclusion than that errors of the refractive media of the eye are answerable for a large number of our every-day headaches, a number quite unsuspected by the profession at large. And in saying this I would wish most particularly not to be misunderstood. I do not for one moment suppose that all headaches are due to ocular trouble—far from it; but I do believe that a very large minority are due to this cause. In one respect I labour under the disadvantage of not seeing general practice, and therefore have not the opportunity of seeing the many varied conditions of health which lead to headache irrespective of a definite cause. I therefore ask to be forgiven if I appear inclined to overrate the importance of the specialty at which I am engaged, and I have the satisfaction of knowing that there are many practitioners who have a vast experience of headache, and that they will be able either to bear me out in my conclusions, or, on the other hand, to correct me.

THE INTERPRETATION OF DISEASE.

By H. CAMERON GILLIES, M.B.

III.

THE LIFE-SAVING VALUE OF PAIN AND DISEASE.

THE value of a thing is properly determined by its utility. When I speak of the value of pain and disease, I mean to emphatically assert the usefulness of these to mankind. Pain and disease are very closely related. The pain is, indeed, the immediate cause of the *dis*-ease. We cannot have pain without *dis*-ease, but we may have disease without pain. Disease, in the latter sense, is an expression for a pathological structural change; but it is not *dis*-ease in the etymological, original, and, I may say, more correct use of the word.[1] I shall not, however, attempt to be too severely exact in the application of these terms, but shall use them with comparative freedom, as of almost identical value, for the purpose of this paper. I do not concern myself with definitions of pain. It is not the Whence nor the How of pain that is of practical interest, but the Wherefore—its meaning, intention, and purpose. Someone—perhaps Sir James Paget—has said with great beauty and truth that "pain is the prayer of a nerve for food." That is perhaps the finest and most comprehensive definition of pain in all our literature, and it is quite sufficient for our purpose. The "textural death" from "privation" calls for sustaining and repairing food. That is pain, and that is its purpose.

[1] "Before King Henry crossed the seas,
And o'er to France he did transfleet
Lest that the Scots should him *disease*,
He constituted captains meet."—CHEVY CHASE.

Digitized by Google

I have, for myself, a very commonplace rendering, or rather paraphrase, of *pain* in the expression, *there is something wrong*. It does not look at all learned or ingenious, but I have found it very useful. I shall employ it in what follows for the sake of brevity and point.

If I take up a too hot poker in my hand, pain comes at once, to tell me in the most convincing manner *there is something wrong;* and I throw the hot poker away at once. If it has not in any way injured the skin, there is no pain now; but if it has, the pain remains till all is right again. Perhaps a "bad blister" is the result. But is not this blister the most beautiful possible provision for saving the deeper parts from injury by interposing a pad of water between the superficial skin and the tissues beneath? The pain and the disease here are surely of the highest value in saving me from worse things, which, without their intervention, I could not escape.

If I get a pin or a treacherous tack into my skin anywhere, pain at once declares *there is something wrong;* and it goes on persistently, and even more loudly as the delay, with the same declaration till the offending thing is extracted—till the wrong is righted,—then all is peace again. A sensation of pain may continue after the removal of the cause, but this also serves the great purpose of ensuring the repair of the injury done. It is the prayer of the nerves of that part for food—for the materials of repair; and it does not leave off till the measure of mischief done is put right—till the *status quo ante* is restored.

Suppose that I have eaten some indigestible or badly cooked food, or partaken too freely of the ten thousand "dishes" that the ingenuity of the modern kitchen devises for the civilised palate. My stomach cannot digest it. It rebels, or rather justly resents the injury. Spasms, cramps, and colic declare that *there is something wrong*. The offending indigestible is vomited perhaps, or a smart dose of physic gets rid of it. The pain ceases, for all is now well.

A healthy man, comfortable in life, with a good digestion and not much to do, drinks too freely of malt liquors and the heavier wines. Notwithstanding the many warnings from his head and stomach, he perseveres in his full living and and in his drinking, till one early morning, very likely after a special indulgence on the previous day, a twinge in the great toe and a cruel pain waken him to tell him *there is something wrong; you must stop that port*. He has gout. He calls on his doctor, and "gets his sewers flushed," as I heard Dr. Alfred Carpenter put it. His clogged systems again flow freely, and if he avoid his malt liquors and his wines and his too much eating, he will keep free from gout and in good health. But if he go back to his old ways, he will certainly have rough teaching sooner or later. His pain and his *dis*-ease are his best friends, if he only knew it.

The case of the spirit-drinker is still more emphatic. He drinks the "devil in solution" day by day and night by night; and notwithstanding that morning by morning a splitting headache tells him *there is something wrong*, he heeds it not, but goes for "a hair of the dog that bit him." He gets up steam at the expense of his physiological capital. His working account is exhausted, over-drawn. He is fast on his way to physiological bankruptcy. His energy gets dissipated, nervous sensibility diminishes, and the value of pain diminishes day by day. At last there comes a time—a terrible time—when he has a headache no longer. The headache goes and all his physical pain. But there come the "horrors" of delirium tremens. Cats, dogs, mice, lice, snakes, scorpions, devils, come to lash him into the conviction that *there is something tremendously wrong*. This is the end of the tether. It is either suicide or some other terrible unnatural death—if not perfect obedience, and recovery even at this very last. Surely it were better to have listened to the headache and the former sufficient warnings of pain than to have incurred this fearful reward of disobedience.

The case for the utility of pain and disease is so far, I think, very plain and easily accepted. It is the valuable active check upon errors and indiscretions that would injure the health and endanger the life of the individual. Let me present the matter from another point of view.

Pain never comes where it can serve no good purpose. Pain is eminently merciful, if I may so put it. That is a fact of so great significance that we cannot easily comprehend all it implies. Say that a man is smashed in a railway accident. If his injuries be such that he *cannot recover*, he suffers no pain at all. He dies of shock, as the surgeons say. But that, I submit in all humility, is a wrong view of the case, a wrong interpretation of the natural facts. The man dies because vital parts of the organism have been destroyed in the collision; and this condition of shock, this insensibility to useless pain, is the most merciful provision that can be conceived.

But to get more light on the matter, say that the man is not mortally wounded, but has received some severe injury—say a compound fracture of the thigh. There is a period of shock here also, *but it passes away after a time;* and then if the limb has not been properly set and fixed, and the wound cleansed and dressed, pain comes with full force to impress that *there is something wrong* which requires to be put right. But if in the period of shock the injury has been properly attended to, there is no pain to speak of after the shock is over. The thing is as right as it can be in the circumstances, and there is therefore no unnecessary pain. So much is this a recognised truth that the surgeon's best proof of having done his work well is the freedom from pain, as the presence of excessive pain after a limb is set is the inevitable evidence that the setting is in some respect at fault—that *there is something wrong*,—and that the limb must be taken down and reset. Could anything be more beautifully admirable than this temporary insensibility to pain?—"shock" as it is called—Nature's time of grace in which the injury should be attended to. I cannot think of this shock, but with the profoundest admiration and reverence; yet our medical traditions, and even our present day literature, declare it an evil or a dangerous state, which should be got rid of, if at all possible. We should be very thankful that it cannot be got rid of till it has served its good purpose. It is strange that we should regard this condition as harmful, which we imitate with the aid of chloroform to enable us to do our work properly. I venture to put it that shock is in direct proportion to the violence of the injury, and inversely as the vitality or capital energy of the individual. Surely this shock is one of the greatest blessings of our existence, when it does away with unnecessary and otherwise unavoidable pain. But if the injury be not attended to in due time—before shock has passed off,—as surely is it a beneficent compulsion that makes us attend to it. That is what the shock and the pain do. I will venture on another very interesting proposition.

The measure of pain which attends an injury or a disease is a prophecy, in that same measure, of recovery. The pain attending an injury or a disease varies as the vitality, as the promise of life. The scratch of a pin will put an infant into convulsions; an old man would perhaps not feel it at all. We see old people and weakly people suffering little or no pain from injuries that would cause acute and serious constitutional disturbance in the young and vigorous. A physician to one of the Paris hospitals for aged women illustrates this well. "They get up in the morning," he says, "and make their beds. They have breakfast and perhaps go about a little. They say they feel tired. They lie down to rest—and die. When the lungs are examined afterwards, they are found so far diseased that life was quite impossible any longer." Yet they suffer no pain at all. Pain in their case would serve no good purpose. There is no pain. Their potential energy is run out; their promise of life is *nil;* they die without any suffering. It is an easy matter to be satisfied that *pain is as the vitality* of the individual, and I follow it no further.[2]

But the *power of repair also is* and must be directly *as is the vitality* and the promise of life. This needs no proof. Therefore, and as plain as anything can be, *pain is in direct proportion to the powers of repair*—that is, to the probability of recovery. My proposition, then, is proved.

The wisdom of our popular philosophy is on this matter, as on several others that could be named, in advance of our scientific attainments. We have heard in the common talk of the people in remote parts of the country how they did not like a depressing disease or a violent injury not attended with pain. They always looked on such a state as ominous; but when the sufferer began to complain it was to them a good sign. It is in our knowledge now that almost all inevitably fatal diseases are not attended with pain. Pain in such cases would serve no good purpose; there is no pain.

Now let me say at once that there are serious exceptions—apparent exceptions—to this law of pain. Say that the injuries to the man in the railway accident are such that he

[2] "The quantity of pain thou feelest is indicative of the quantity of life, of talent, thou hast; a stone feels no pain."—*Carlyle, Journal*, 1830.

Digitized by Google

does not die in the first period of shock, but recovers sensibility and suffers much pain, but dies. That looks like useless pain and suffering, and fatal to my theory. Let us see. Fifteen or twenty years ago, that is almost certainly what would have been the course of a bad compound fracture of the thigh—shock, recovery to sensibility, great suffering, and death. But in our day we never look for the death, in a healthy man, from compound fracture of the thigh. Has this pain, then, this apparently useless suffering, ending in death, which had through long centuries rang in our pitying ears, that *there was something wrong* in our treatment of compound fractures—has it been of no avail, to no purpose? Did it not lead Joseph Lister to put the matter right some years ago, from which time we may justly say that there has been no such needless pain, no such suffering? The life-long devotion of valuable men has extended the recovery in our lives very much even within these last twenty years, and there is every reason to believe that it shall be yet extended a good way further.

To my mind, then, as long as that limit is not attained by care and skill at which for any disease recovery is in the natural intention impossible, so long must such acute physical pain as seems to be outside this law of purpose mean that *there is something yet wrong* which must be put right. This must dispose of every seeming exception, and pain that is apparently purposeless must be taken to indicate something wrong, which we do not as yet understand, and are therefore not able to put right. Pain is in these therefore our invaluable stimulus or incentive to earnest effort. We may be quite sure that when we understand its meaning we can put it right, and pain shall cease.

Pain comes at the right time. This may seem an unnecessary assertion if it be proved and accepted that pain always comes for good. Whenever it comes must be the right time. But I wish to bring the point into prominence for an interesting purpose. If Mr. B—— had continued with "nothing particular the matter," daily and steadily going down hill, he would most certainly have died. But his pleurisy came to save him. So severely, however, did the acute stage draw on the possibilities of his physiological resources that it was just a toss whether he would get round the corner. He did go round, but without a single ounce, as would seem, of power to spare. It must be manifest that if he had gone a few days later in being compelled to take care of himself, he could not have recovered. Is it not our experience that all distinct cases of acute disease are similar in this respect—that when they "get the turn" they have nothing to spare? And is it not very interesting that all kinds of acute disease have approximately the same period? Does it not indicate that there is something like a *disease point* in the constitution of every individual, below which the energies of the body cannot be exhausted without danger and without the physiological protest of acute disease? The point is analogous to, and perhaps identical with, the *recovery point*, which I referred to in the case of accidental injuries. As the *melting point* of ice is the *freezing point* of water, so, to my mind, the point at which the natural intention is upwards towards recovery or downwards towards death is one and the same. There is in proof of this the other interesting fact that the period of indisposition or of declining health before an attack of acute disease is approximately and relatively equal to the period and care necessary to recovery. The way up hill is the same distance as the way down.

I have had under my care a young business man—a man of great force and fine *go*, with a highly-strung temperament. His physiological expenditure is consequently very high. He is subject to most violent headaches and acute feverish attacks, lasting from one to three days; but in that short time he loses several pounds in weight, so severe is the attack. That man is as satisfied as I am that his headache is saving his life, for the attacks never come but when he has overdone himself; and as surely as he so does the attack comes and lays him up. This is the natural protest against his physiological extravagance. It pulls him up sharp—in time, and teaches him most effectively that he must not forget his body in his business. I would not prevent these headaches if I could; I am sure they save him from worse things. Indeed, he understands the matter so well now that he takes the first monitions and saves himself from even his headaches; and he would be the first person to affirm that they always come at the right time, notwithstanding they are often inconvenient and always disagreeable.

Bradley, K.

PILOCARPINE IN TWO CASES OF PUERPERAL CONVULSIONS; DEATH IN ONE CASE.

By ROBERT KIRK, M.D.Ed., F.F.P. & S.Glasg.,
OUT-DOOR PHYSICIAN-ACCOUCHEUR TO THE GLASGOW WESTERN INFIRMARY.

THE success which has attended the use of pilocarpine in some cases of puerperal convulsions renders it important that failures should also be noticed. I therefore put on record the following two cases, in one of which the drug did not avert a fatal result.

I was hastily summoned one day about 1 P.M. to see a primipara, aged twenty-five, in convulsions. I found that her ordinary medical attendant, Mr. Young, was temporarily absent, but that he had seen her in the forenoon after the onset of the eclampsia, and had ordered fifteen grains of chloral, which, however, the patient had almost immediately vomited. On my arrival the patient was in a comatose state, but very shortly afterwards she was violently convulsed. She was said to be in the eighth month of pregnancy, and there was considerable, but not excessive, anasarca of the face and lower extremities; skin cool; pulse 90, full and resistant. At this juncture Mr. Young arrived, and he informed me that the urine was albuminous, and that labour was in progress. We agreed to try pilocarpine, and accordingly a disc containing one-third of a grain was administered hypodermically. I then took my leave, but afterwards learned from Mr. Young that though the most profuse perspiration had ensued, and had lasted for several hours, the convulsions and coma were not in the least degree modified. The child was expelled (stillborn) some hours after my visit, and the mother died the same evening. I should add that when the failure of the pilocarpine became evident to Mr. Young, he again administered chloral.

The second case occurred in connexion with the out-door midwifery department of the Glasgow Western Infirmary, and is interesting as an instance of recovery from purpura hæmorrhagica during pregnancy and complicated with convulsions. The patient was a multipara, between thirty and thirty-five years of age, in about the seventh month of gestation, and was said to be a habitual drunkard. I first saw her about 3 P.M. Her face was of a dusky hue, and there was an ecchymosis on the lower eyelid on the right side, as if from a fall or blow. There were numerous purpuric spots, about the size of small peas, on the forearms and legs, and the skin generally presented the same dusky hue as the countenance. The surface was quite cool; pulse 80, strong and full. The catheter drew off one or two drachms of highly bloody urine; but there was no œdema of the legs or face. Every ten minutes or oftener the patient was seized with severe general convulsions, remaining drowsy, but capable of being partially roused in the intervals. Labour was in active progress, and the os moderately dilated. I regarded the prognosis as not very unfavourable, apart from any kind of treatment, but at the urgent entreaty of relatives that something should be done, a disc containing one-third of a grain of pilocarpine was injected hypodermically. The child was born about half an hour afterwards, and had plainly been dead for some days. Copious perspiration resulted in the mother; the convulsions soon ceased, and she made a good recovery, with the subsequent aid of iron and small doses of turpentine.

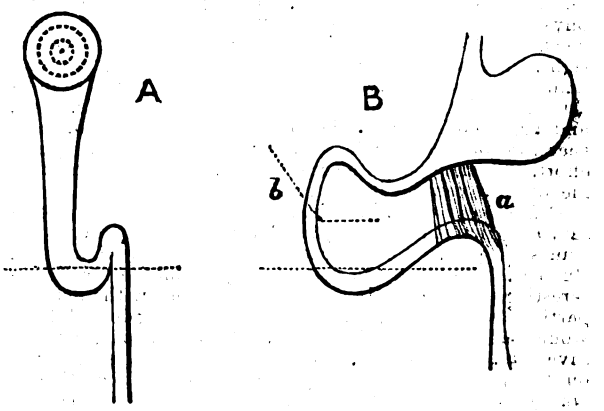
Remarks.—I am scarcely disposed to regard the result in the latter case as due to the pilocarpine, believing that it would probably have happened independently, while it got a fair chance in the first case, which was quite a typical one and not of unusual severity. I may, perhaps, refer here to one or two points which seem of some interest in connexion with puerperal eclampsia. In the first place, every practitioner should make it an invariable rule to ask every female who comes to engage his services at her confinement whether her legs are swollen, and if so the urine should be at once examined, and proper treatment, if necessary, adopted. It is remarkable that the patient herself will seldom volunteer this information. I cannot but here record my strong conviction of the superiority of a diuretic to a diaphoretic system of treatment in this and other forms of acute nephritis; this was much insisted on by the late Dr. Hughes Bennett and others, but still seems to be a moot point amongst authorities. Another point is as to the actual

Digitized by Google

moment of the onset of eclampsia. Is this more apt to occur during sleep and in the recumbent posture than in the erect posture and when the patient is awake? When we consider that very considerable œdema of the legs, in pregnant females more especially, will often almost entirely disappear in a single night after rest in bed, it seems not unlikely that the recumbent position may predispose to an attack. But the question has a practical bearing beyond this. When the patient recovers, we know how rapidly the anasarca disappears and free diuresis takes place. But in this process there are two distinct stages which do not necessarily keep pace with each other, and in point of fact probably never do so. The absorption of the effused serum may occur to a considerable extent, though the kidneys may altogether fail to eliminate it. I am inclined to believe that in this lies a prime element of danger in these cases. I have never seen a patient die of convulsions in actual labour, even when this has extended over twenty-four hours, and such an occurrence is surely comparatively rare; every death I have seen took place some hours after delivery. The efficacy of bloodletting, and to some extent that of pilocarpine, from the considerable elimination of fluid in the perspiration effected by the latter, may perhaps be partially explained in this way. But if so, would it not be better, when called to a case in which there is considerable œdema of the legs, to at once drain the latter of serum by a few incisions, or by Southey's tubes? I mean to put this in practice in the first suitable case.

THE DUODENUM: A SYPHON TRAP.

BY MAYO COLLIER, M.S. LOND., F.R.C.S. ENG.,
SENIOR ASSISTANT-SURGEON, NORTH-WEST LONDON HOSPITAL; ASSISTANT DEMONSTRATOR OF ANATOMY, LONDON HOSPITAL MEDICAL COLLEGE.



WE may take it for granted that all gases generated in the jejunum, ileum, and large intestines pass onwards towards the anus, and there sooner or later escape. Fetid gases—except those generated in the stomach and duodenum—never pass upwards, not even during vomiting due to hernia, obstruction, and other causes. Physiologists, it would appear, have never busied themselves to find an explanation for this apparent breach of the laws of gravity. The intestinal canal is a tube with various dilatations and constrictions, but at no spot except the pylorus does the constriction completely obliterate the lumen of the tube, and here only periodically. It is perfectly evident, then, that, unless some system of trap exists in the canal, gases are free to travel from below upwards in obedience to the laws of gravity, and would, as a matter of fact, sooner or later do so. From the straight course and vertical position of the œsophagus, a very slight pressure of gas in the stomach easily overcomes the closure of its cardiac sphincter and allows of escape. When the stomach has digested its contents and the pylorus is relaxed, gases generated in the duodenum can and do ascend into the stomach and so escape. Normally no fetid gases are generated in the stomach or duodenum. If we follow the course of the intestines down, we find that the duodenum presents a remarkable curve.

Now, there are some points of great interest in connexion with this remarkable, almost circular, curve of the duodenum. In the first place, this curve is a constant feature in all mammalians. Mr. Treves says it is one of the most constant features in the anatomy of the intestines in man, and, speaking of mammalians in general, that the curve of the duodenum varies in shape, but is never absent, becoming more complex in some of the higher primates, but seldom less distinct than in man. In birds the duodenum always forms a long loop embracing the pancreas.

A second point of great interest is the absolute constancy and fixation of its terminal portion at the point of junction with the jejunum, more correctly termed second ascending or fourth portion. Mr. Treves says that this fourth portion is never less than an inch, and is practically constant. It extends along the side of the left crus of the diaphragm opposite the second lumbar vertebra, and is there firmly fixed to the front of the aorta and crus of the diaphragm by a strong fibro-muscular band, slinging it up and absolutely retaining it in position. This band has been termed the "musculus suspensorius duodeni," but is chiefly composed of white fibrous tissue, and is more of the nature of a ligament than a muscle. This ligament is always present, and its position is never altered. The curve of the duodenum may descend as far as the iliac fossa, but the terminal portion is always maintained by this band in its normal position.

Another point of great constancy is the position of the pancreas and its relation to the curve of the duodenum. The duodenum always curves round the head of the pancreas, and is, as it were, moulded on it and retained in position by it. In birds the duodenum always forms a long loop embracing the pancreas. Further, the ducts of the liver and pancreas always open into the centre of the duodenum, either separately or by a common opening.

Now, the absolute constancy of the curve of the duodenum, the complete fixation of its fourth portion, the position of the pancreas, and the place of entry of the ducts of the pancreas and liver, are all component parts of a syphon trap, whereby gases generated below the duodenum are prevented from passing upwards. A reference to the accompanying diagrams will make this quite clear. A is a diagram of a

syphon trap copied from Parkes' hygiene. B is a very diagrammatic outline of the stomach and duodenum. *a* is intended to mark the position of the fibrous band, or musculus suspensorius duodeni; and *b* the position of entry of the ducts of the liver and pancreas. The duodenum, then, is a syphon trap, and a most efficient one. Now, the efficiency of a syphon trap depends not only on its shape, but what is absolutely essential is that the curve must be kept constantly full of fluid, without which it ceases to be a trap, and would allow gases to ascend freely. The position of the place of entry of the ducts of the pancreas and liver assures that this *sine quâ non* shall be present. The discharge of the secretions of the pancreas and liver, although more active during and after feeding, is practically constant, and so ensures in an admirable manner that the curve on which the efficiency of the trap depends shall be constantly kept full, not only with fluid, but, as I would suggest, antiseptic fluid. There is no other trap in the intestinal canal, but the peculiar position of the colon would no doubt have more or less effect in preventing gases ascending through the ileo-cæcal valve.

New Cavendish-street, W.

A PHASE OF ENTERIC FEVER,

WITH NOTES OF FOUR ILLUSTRATIVE CASES.

BY JOHN CLERK, M.B.,
PHYSICIAN SUPERINTENDENT TO THE JOINT BURGHS FEVER HOSPITAL, KNIGHTSWOOD, GLASGOW.

ACCORDING to the report given in THE LANCET of February 13th, 1886, the greatest diversity of opinion prevailed among the members of the Medical and Chirurgical Society in regard to the true nature of so-called typho-malarial fever. Out of an analysis of eighty cases at Suakim, seventy were of the ordinary enteric type, but some "were so modified by climatic causes as to merit the designation of malarial-enteric." One member thought the cases might be of a dysenteric nature, while another held that the typho-malarial form departs in the most complete way from enteric fever, "being really a distinct fever that

Digitized by Google

simulates typhoid only to a very limited extent." Those who are cognisant of the vagaries of enteric fever will feel inclined, I think, to agree with the following remark gleaned from the same report. "The cases of fever seen in tropical climates were, in his experience, true enteric fever, presenting its clinical features during life, and its morbid appearances in fatal cases. As regards typho-malarial fever, there was no evidence of its existence as a new and perfectly distinct disease, although of course a malarious subject might be attacked with typhoid fever, and exhibit symptoms of both diseases." This surely is the common sense view of the matter. The term typhoid (meaning, *like typhus*) was adopted when the characteristics of these two diseases were insufficiently known, and led no doubt to a great amount of confusion of thought, the one malady being often looked upon as a variety of the other. In the present instance, the adoption of the term "typho-malarial" looks very like a repetition of the typhus-typhoid mistake. That the malarial poison may co-exist with enteric in the same person, just as the poison of scarlet fever may, no one need doubt, but this surely is no reason why such co-existence should give rise to compound names which seem to point to a combination of two poisons in the same individual, giving rise to a disease different in its nature from either of the two original ones. If, as is stated in a recent number of THE LANCET,[1] the temperature in typho-malarial cases is generally different from that of enteric fever, if the absence of rose spots is invariable, and if there is no ulceration of Peyer's patches, nor of the solitary glands of the ileum, then typho-malaria is distinct enough from enteric fever and deserves a new name to distinguish it from other maladies, but only when it is proved to be a new disease. Until the mass of evidence is sufficient to put this beyond question it is certainly wiser to leave it without a name than give it one which can only lead to error and confusion. In describing the Suakim fever (typho-malaria) Dr. Squire makes mention of the following among other symptoms: "The onset is sometimes more sudden than that of enteric fever, and bilious vomiting is often an early and persistent symptom. Diarrhœa is frequently but not invariably present, the stools being greenish, or resembling those seen in enteric fever." Cases presenting such symptoms as these are sometimes also designated "bilious-remittent," but the bilious-remittent are considered by such an authority as Murchison to be true cases of enteric fever. To solve such questions as present themselves in the foregoing remarks an accumulation of evidence is absolutely necessary—evidence as to symptoms during life and morbid appearances after death; and it is with the view of aiding inquiry that I venture to give short notes of the following four cases, of which bilious vomiting and green motions formed very characteristic features.

CASE 1.—T. G——, aged twenty-nine, was admitted into the Joint Burghs Hospital on September 25th, 1886. He stated that he was in his ordinary health on Sept. 22nd. On the 23rd he went to his work, but had to come home owing to severe headache, with vomiting and purging. On the 24th the stools were, he says, of a dark colour, and he had severe pain over the abdomen.—Sept. 25th (day of admission and third day of illness): Purging continues; no pain and no gurgling in right iliac region.—Fourth day: Since 8.30 last evening till now, 11 A.M., he has passed eight motions of about four ounces each; five of these bloody; three, a mixture of blood and greenish liquid; sediment of motion composed of flocculent mucus, small clots of blood and thin epithelial flakes tinged of a beautiful bright green. Six motions of about two ounces each had been passed during the day, mostly green. Morning and evening temperature 99·6°; pulse in the evening 108.—Fifth day: Two dark jelly-like motions passed during the night, about two ounces each. Pain referred to right of umbilicus to-day. Pupils slightly less than normal.—Sixth day: Passed two slight dark motions during the night; all pain is gone.—Seventh day: Three loose motions during the night; no appearance of blood in any of them. Pulse 90; temperature 99°. Tongue has a whitish coating of fur in the centre; no pain in abdomen; pupils dilated; seems much better.—Tenth day: Has continued to improve, and is now quite recovered.

CASE 2.—J. C——, aged twenty-seven, labourer, was admitted on Sept. 29th, 1886 (said to be the eighth day of illness). He says he has had severe purging.—Ninth day: Six loose green motions during the night. Two rose spots on abdomen. Evening temperature 103°.—Tenth day: Twelve loose green motions during last twenty-four hours. Temperature 103°.—Eleventh day: Nine loose greenish-yellow motions in last twenty-four hours. Three loose yellow motions during the day, and at 4.30 P.M. a green loose motion with a fair quantity of blood, and three more of the same nature between that time and 9 P.M. Abdomen distended. Temperature 102°; pulse 120.—Twelfth day: Passed three loose motions containing considerable quantities of blood. Temperature 102°; pulse 114.—Thirteenth day: Rested well during the night. No motion. Pulse intermits.—Fourteenth day: Three motions, one light green, two a mixture of green and yellow with a fair quantity of blood.—On the fifteenth day, four green motions; on the sixteenth day, three bloody and two green; on the seventeenth day, two loose yellow motions. On the twenty-eighth day of illness the evening temperature was normal and the diarrhœa stopped. The man made a good recovery.

CASE 3.—G. C——, aged twenty-two, domestic servant, was admitted on April 27th, 1886. Said to have been taken ill on April 18th. Complained of headache, pain in the small of the back, and general malaise. This continued during the following week with failure of appetite and occasional retching. On admission no rose spots were noticed. The tongue was covered with whitish fur, and the patient felt very thirsty.—Eleventh day: Gurgling and slight pain in right iliac region. Suffers from coldness of feet alternating with almost unbearable flushes of heat.—Twelfth day: Passed a restless night. Tongue dry, with brownish fur, and papillæ of apex enlarged. Three rosy spots on abdomen.—Thirteenth day: Three fresh rosy papules to-day. Strawberry appearance of tongue, very marked. Passed two loose green motions during the day. Evening temperature 104°.—Fourteenth day: Four green motions in the last twenty-four hours, and the patient vomited some green fluid last night. Retention of urine gave rise to severe abdominal pain; relieved by hot fomentations.—Fifteenth day: Two green motions were passed in the last twenty-four hours, and she vomited freely a liquid "green as grass." Feels very sick. A few more lenticular rose spots to-day.—On the sixteenth day she passed five loose green motions; on the seventeenth three; on the eighteenth and nineteenth days very little; on the twentieth day four in the twenty-four hours. After this she gradually improved, although occasionally she had attacks of bilious vomiting and passed green stools until the thirty-fourth day, when she had a relapse, of which she died on the forty-sixth day of her illness. Though the diarrhœa was not at any time excessive, the motions were markedly green, or else slightly tinged with green, between the thirteenth and twentieth days. During the period of relapse the bowels were constipated, and only on three occasions did she pass small, slightly greenish motions. As many as thirty-five rose spots were counted on the chest and abdomen alone at one time, and with the relapse there appeared a crop of rosy papules of small size.

CASE 4.—H. C——, aged seventeen, was admitted on April 29th, 1886, but it was impossible to get a reliable history of her illness. She was said to be ill for more than three weeks before admission. There was gurgling and slight pain in the right iliac region, and two or three rose spots were marked on the abdomen. Her bowels were slightly constipated, but she had had on several occasions severe attacks of bilious vomiting, which left her very sick, and with a bad taste in her mouth. It is unecessary to go more into detail. At the post-mortem examination the ileo-colic valve and adjacent portions of ileum and large colon presented the usual ulcerated appearance.

The presumption in favour of Case 1 being enteric was that he came from an infected locality, but there was no eruption, and the temperature was not characteristic. Of the other three there was no doubt.

[1] Jan. 8th, 1887.

BEQUESTS TO THE MONTROSE INFIRMARY.—The late Mrs. Winifred Nicol, formerly of Brighton, has directed that after the death of her husband the clear residue of her estate, estimated at £5900, is to be divided equally amongst thirteen hospitals and charities, of which the Montrose Infirmary is one. Mr. Nicol, who is eighty-four years of age, disputes the will. The late Misses Trail of Aberlady have bequeathed £500 to the same institution.

CASE OF

ACUTE ASCENDING PARALYSIS; PARTIAL RECOVERY.

BY J. LEWTAS, M.B. LOND.,
INDIAN MEDICAL SERVICE.

As cases of acute ascending paralysis are of somewhat rare occurrence, and as the following case differed in some of its features from the type described in text-books, I venture to think that a short account of it will interest some readers of THE LANCET.

S. S——, a man fifty years of age, came to hospital on Oct. 19th, 1886, complaining of pains about his shoulder blades and in the back of his neck, attended occasionally with a slight degree of fever. Little importance was attached to what appeared to be a case of muscular rheumatism. No symptoms of nervous disease declared themselves until five days after his admission—viz., on Oct. 24th, when, on rising in the morning, he found that he could not in walking lift the right foot clear of the ground; he either dragged the foot, or else, to avoid doing so, had to swing the entire limb outwards from the hip. Sensation in this leg was unaffected; the right patellar-tendon reflex was exaggerated. The left leg was free from nervous symptoms of any kind. The pains in the upper part of the back mentioned above continued. On Nov. 1st a rather large vesicle ("bulla") appeared suddenly on the front of his left patella, and burst on the same day, leaving a purple, discoloured base. On the 3rd he noticed that he sometimes passed urine unconsciously in bed, and at other times that, although conscious that he was about to pass urine, he was yet unable to restrain it if a urinal was not brought quickly. On the 6th a second bulla appeared behind his left thigh. Up to this date the left leg had continued free from paralysis, but that of the right had so far increased that he was now unable to move it when walking, or to draw it up when lying in bed. On the 7th both motor and sensory paralysis began to appear in the left leg. On the 9th his state was as follows:—Tactile sensation was entirely absent on the left side from the toes to a point half an inch below the nipple; while on the right side it was absent from the toes to a point four inches below the nipple. There was a band of hyperæsthetic skin at the upper limit of these areas of anæsthesia. Sensibility to pain was absent throughout both lower limbs, and as far upwards as the iliac crests on both sides. A current from fifty Leclanché elements was, however, painfully felt throughout both legs. Paraplegia was absolute; the legs were drawn up upon the thighs, and these towards the abdomen. Both urine and fæces were passed unconsciously. The patellar-tendon reflex was lost on both sides. The disease seemed to be of syphilitic origin, as he had contracted syphilis two years before, which was followed by sore-throat and an eruption.

On Nov. 7th the man was put upon a course of bichloride of mercury, with iodide of potassium. This specific treatment was soon followed by a marked improvement. On Nov. 11th, being the eighteenth day since the onset of paralysis, tactile sensibility had returned to both sides of the chest and abdomen, but not to the legs; the knee jerk was still absent on both sides. About this time he began to complain of acute pain in the skin over the right hypochondriac region, and this unaccountable symptom persisted for nearly a fortnight. On Nov. 12th two bedsores appeared over the sacrum, one on each side of the middle line. On the 13th and 14th his abdomen became tensely tympanitic, and his chance of recovery seemed small, as his breathing was much interfered with. This distension, however, yielded at last to assafœtida and enemata. On the 15th sensation returned in both legs, and he was able to move slightly the left ankle joint. On the 17th the motor paralysis of the right leg was still absolute, but the knee jerk on that side had returned, while on the left side it was still wanting. On the 18th, with much effort, he could just move the toes of his right foot. About Nov. 15th his left foot and ankle became œdematous; this œdema, which did not extend above the ankle, disappeared in about four days. On the 19th another vesicle appeared on the outer side of the left leg, about midway between the knee and the ankle. The raw surfaces left by previous vesicles had all become ulcers, which had extended both in depth and area. The mercurial treatment was partly suspended for a few days in consequence of what appeared to be threatening salivation, but as a partial relapse of all, or nearly all, the nervous symptoms ensued, the treatment was resumed in full. On Nov. 26th the knee jerk had returned on the left side also. From this date onwards he continued to regain motor power in both legs. On Dec. 16th, having been fifty-three days in hospital, the patient was sent to his home; he was then able, unassisted, to move himself in bed from a lying to a sitting position on the side of it, but could not stand up; he was also sensible of impending evacuations either of rectum or bladder, and able to provide against them, although not able to postpone them. On Feb. 24th, four months after his seizure, I heard that he was able to walk slowly with the support of a stick.

Remarks.—That this disease was caused in some way by syphilis is proved, I think, by the history, by the early and rapid improvement under mercurial treatment, and by the temporary arrest of this improvement during a temporary diminution of the dose of bichloride of mercury. The imperfect symmetry of the symptoms was remarkable; for example, the right leg was paralysed when the left was still unaffected; yet the knee jerk disappeared first on the left side, and did not return on that side until a week after it had returned on the right. Again, whereas three bullæ and subsequent ulcers appeared on the left limb, none appeared on the right. The two bedsores on the sacrum were, however, symmetrical. Between Oct. 24th and Nov. 2nd there was no elevation of his temperature, but from Nov. 2nd to the 13th there was a daily evening rise averaging 2°, but on two occasions amounting to 5° above the normal. A further discussion of the case would be out of place in a clinical record; but I would notice, in conclusion, two variations from the type of this affection as described by Drs. Gowers and Ross—viz., the occurrence of several so-called bedsores and the considerable loss of sensation. The bedsores had the characters distinctive of those which occur in some diseases of the spinal cord; they appeared suddenly, their contents were dark-coloured, the raw surfaces left when the bullæ burst became spreading ulcers, and most of them occupied situations such that pressure could have had no part in causing them. Again, the loss of sensation, although transitory, was well marked. Yet Dr. Gowers[1] says, regarding the former, there is "no tendency" to their occurrence, and, regarding the latter, "there is no considerable loss of sensation." With respect to "a malady so rare that experience accumulates slowly,"[2] universal statements can hardly yet be hazarded.

A CASE OF

ABSCESS OF THE LIVER IN A CHILD THREE YEARS AND A HALF OLD.

BY J. FARRELL EASMON, M.D., &c.,
RESIDENT SURGEON, ACCRA; ASSISTANT COLONIAL SURGEON AND ACTING CHIEF MEDICAL OFFICER OF THE GOLD COAST COLONY.

THE patient, Affuak D——, was brought to me at my official quarters on the morning of Jan. 20th, 1887, with the following clinical history. Three weeks ago a swelling was noticed for the first time in her right side, and this had been getting larger ever since. Some six weeks before, the patient suffered from *artiridi* (Accra) or "bilious" fever; the fever came on every evening, accompanied with much shivering, and ending in profuse perspiration and the discharge of high-coloured yellow urine. She was losing flesh daily, and latterly vomited whenever food was taken. She complained of no local pains and had never had dysentery (*for-keh-lah*, Accra) since she was born, in May, 1883. She allowed her mother to touch the tumour freely, but would not suffer me to get near her for purposes of examination.

I admitted her the same day into the General Hospital (new site) under my care, and with the assistance of my colleague, Dr. Woodburn Heron, put her under chloroform. Examination revealed a large, tense, prominent tumour occupying the entire right hypochondrium, and extending inwards into the epigastric and downwards into the hypogastric regions, with a distinct bulge anteriorly below the ribs. The tumour was dull on percussion, and there were

[1] Diseases of the Nervous System, vol. i., p. 276. [2] Ibid., p. 279.

Digitized by Google

obscure signs of fluctuation. Introducing the finest needle of the aspirator I obtained pus; I now withdrew this and introduced the second largest aspirating trocar and drew out nine ounces of thick yellow pus, odourless and without clots. The abscess cavity (a single large one) was then thoroughly washed out with ten ounces of a solution of chloride of zinc (half a grain to the ounce), an injection made of successive portions of two ounces at a time, and finally two ounces of the solution left in. An antiseptic pad was placed over the puncture, and a flannel bandage put firmly on around the abdomen and thorax. Complete anæsthesia was maintained throughout the operation. The patient was put on beef-tea diet and milk *ad lib.*, with five-grain doses of chloride of ammonium three times a day. At my evening visit I found the patient up in bed and evidently quite contented. She had complained of no pains. The temperature from 97° before the operation had risen to 99° in the afternoon, but there was no feverish feel about her.

Jan. 21st.—8 P.M.: Passed a good night; slept well; one stool this morning. Temperature 98°.—5 P.M.: Temperature 101°. Feverish and restless; no stool since last note; skin dry. Ordered: mist. alb. (hosp.), six drachms; syr. simpl., six drachms; ft. hst. statim. Tepid spongings later on if necessary.

22nd.—The temperature continued to rise last night till midnight, when it reached 103°. As the skin was acting fairly well, the tepid spongings were omitted; no rigors. After midnight the bowels began to act, and with their action the temperature began to fall, till at 6 P.M. it was 98°. During the day the bowels acted four times. Quinine in doses of one grain and a half, with three minims of dilute hydrochloric acid, were now added to each dose of the ammonium chloride mixture. Evening temperature 99°.

23rd.—Morning temperature 97°; evening temperature 99°. Three stools during the day.

24th.—Morning temperature 97°; evening temperature 100°. Three stools during the day. The tumour is slightly increased in size.

25th.—10 A.M.: Temperature 99°. The patient was feverish and restless during the night; no distinct rigors, however. Has had two stools during the morning. Under chloroform the abscess was aspirated, and five ounces of creamy yellow pus, without any perceptible smell, evacuated. The cavity was thoroughly washed out with a solution of chloride of zinc of the same strength as before, and an ounce of the solution finally left in.—5 P.M.: Temperature fell to 98° after the operation, but rose again to 99° during the afternoon. The patient has had three stools since 10 A.M. Seems cheerful.

26th to 29th.—With an average number of three stools each day, the temperature varied between 97° and 99° on the 26th, 98° and 100° on the 27th, and 98° and 103° on the 29th. The general condition up to the evening of the 29th seemed satisfactory; the patient cheerful, and taking her food well.

30th.—10 A.M.: The patient was feverish and restless all night; no rigors, however, or profuse perspiration. The skin at present is hot and dry, the temperature being 100°, and the little patient looks altogether ill. She was put under chloroform and the abscess again aspirated; six ounces of thick, brownish-yellow, fetid pus, with numerous flakes of broken-down liver tissue and clots, were with some difficulty evacuated through the largest size aspirating trocar. The cavity was then thoroughly washed out with (first) twelve ounces of a solution of chloride of zinc, one grain to the ounce, and finally with about ten ounces of a solution of half the strength, two ounces of which were eventually left in. Slight hæmorrhage occurred in the abscess towards the end of the operation. And now the question of a free opening and insertion of a drainage tube again presented itself, but this time more forcibly. Taking into consideration the extreme restlessness of the little patient, the difficulty invariably experienced when she was being put under chloroform, the violent contractions of the abdominal muscles, which on the first occasion threatened rupture of the wall of the abscess, and as the cavity had been thoroughly washed out, I decided not to make a free incision. An antiseptic pad of flannel bandages was accordingly applied as before.—5 P.M.: Temperature 101°. Three stools since last note. The child was up playing with her sisters, and apparently quite happy.

The next and the following days the temperature oscillated between 98° and 101°, the bowels acting regularly. On February 1st the dose of quinine was increased to three grains three times a day. On the evening of this day the temperature rose to 103°, but after this it gradually fell, with slight oscillations, till Feb. 8th, when it was 98°; and from this date it remained normal till the patient left the hospital. She rapidly gained flesh, and all signs of further liver trouble disappeared.

On Feb. 7th, and also on the 20th, before discharging her from the hospital, I made a careful examination of the liver, but all signs of recent mischief had disappeared. Seen five weeks after her discharge from hospital, she had gained flesh and was looking quite well.

Remarks.—Besides being interesting as a sequel of malarial fever—an uncommon result on the Gold Coast, so far as my experience extends,—this case is noteworthy on account of (1) the age of the patient, (2) her sex, and (3) the successful result of the treatment. For these reasons I desire to place it on record.

ST. THOMAS'S HOSPITAL.

A CASE OF HYDROPHOBIA; DEATH; NECROPSY.

(Under the care of Dr. ORD.)

THIS case is chiefly remarkable for the long period of time which elapsed between the inoculation and the development of the disease, which ran an acute course. It would appear that in the majority of instances hydrophobia develops during the four months which immediately follow the infliction of the bite; in this case it was apparently two years. Much temporary relief was obtained by the use of the ether spray applied to the back of the neck. For the following account we are indebted to Mr. S. W. Wheaton, house-physician.

The patient, aged six years and a half, a well-nourished boy, was admitted on May 16th. He was bitten over the left eye two years previously by a dog supposed by the bystanders to be mad. The wound was very slight, and was not treated in any way. After complaining of tenderness over the left eye for some days, he was observed on the evening of the 15th to be rolling on the floor and complaining of headache; he also complained of a pain in the abdomen and toothache on the left side. On being put to bed he refused food, and when anything to drink was brought near him he struggled and tried to knock it over. On the 16th he began to make a peculiar cry, and had "catching of his breath"; he became very excited when touched or when offered anything to drink. He was therefore brought to the hospital.

When admitted the boy was in a condition of great excitement and extreme terror; the pupils were widely dilated; he was constantly looking about wildly, and was very excited when anyone approached him, but after a time quieted down. The respirations were very irregular, and occasionally there were spasmodic contractions of the diaphragm, producing a peculiar noise, like a long-drawn hiccough, ending in a shrill scream. He lay upon his back, with legs drawn up and head retracted; there was active rigidity of both arms and legs. When anything was offered him to drink he jerked about in the bed violently, and tried to knock it over with his hands; directly fluid entered the mouth it was ejected violently, his face became livid, the pupils dilated, respiration interrupted, extremities rigid, and back arched. There was a small superficial scar over the left eyebrow, but no redness over it; also bright injection of the fauces, but no swelling; the submaxillary glands were a little enlarged, but not tender; but pressure over the larynx was especially painful. When micturating he had an attack of general convulsions; the urine contained a large amount of albumen, but no sugar, and a deposit of

Digitized by Google

ammonium urate was present. Bowels confined. He was fed by the nasal tube, and bromide of potassium was given.

On the 17th the patient continued still in a condition of wild excitement, and the sight of a cup of milk produced general convulsive movements, which began to recur every ten minutes; in the intervals he was quiet, would talk to the nurse, and complained still of toothache. At 11 A.M. the convulsions became more frequent, and he was constantly ejecting frothy fluid from the mouth. The ether spray was applied to the back of the neck, after which the convulsions ceased, and he drank for the first time by the mouth. He remained quiet until 12.30, when the paroxysms returned, and ether spray was again used; after this he was quiet until 4 P.M., when he had a severe convulsive attack, with great rigidity of arms and legs, retraction of the head, and arching of the back, and was ejecting frothy mucus from the mouth mixed with grumous fluid. The ether spray was applied again, but this time, on feeding, some of the fluid was ejected from the mouth. After this he spoke sensibly, was much amused with a watch and a penny, but said that the bed was full of spiders. At 6 P.M. he was again seized with general convulsive movements, and vomited a large amount of grumous fluid; the pupils became greatly dilated; he appeared to have hallucinations, laughing and looking about wildly. Respiration gradually ceased, the heart continuing to beat for nearly one minute after the last expiration.

At the post-mortem examination nothing abnormal was found except great congestion of the organs, especially the lungs.

HALIFAX INFIRMARY.

PURULENT DISCHARGE FROM THE EAR, FOLLOWED BY DIFFUSE SUPPURATIVE MENINGITIS; DEATH; NECROPSY.

(Under the care of Dr. S. C. SMITH.)

WE are indebted for the notes of this case to Mr. J. P. Gray, house surgeon.

Thomas M——, aged twenty-six, admitted April 22nd, 1887. Has had purulent discharge from the ear for ten years. A week before admission he began to have severe pain just behind the right ear, and on the night before admission he first noticed that he could not shut his right eye.

On admission the man was pale but well nourished, with a rather anxious expression. There was a profuse offensive discharge from the ear. At the bottom of the meatus was a prominent red granulation. He was quite deaf in this ear, and had been so for several years. A watch, however, placed on the head could be heard distinctly. He had total right facial paralysis. He answered questions readily, and had no hemiplegia. Urine: sp. gr. 1024; acid; no albumen or sugar. Temperature 101·2°.

He continued in this condition for three days, his ear being syringed out frequently. The discharge was still very profuse.

April 26th.—The temperature had suddenly risen to 104·2° this morning. Is dull and apathetic, and becomes confused when asked questions. Pupils equal and act to light.

27th.—Patient has become semi-comatose. Plantar reflex lost on left side, and partial loss of sensibility in left leg, but no loss of power; no loss of power or sensation in left arm. Delirious at intervals. The same evening the left leg had become paralysed and completely anæsthetic. Left arm had lost power, but did not seem to be anæsthetic at all. Accordingly, Dr. Smith trephined, at 7 P.M., over the mastoid cells with a one-third of an inch trephine. No pus was, however, reached. The head was shaved and the ear syringd out with a 1 in 20 carbolic lotion and stuffed with iodoform, in order to make it as aseptic as possible, with a view to possible trephining higher up on the following day. Temperature 103·8°.

28th.—Patient completely comatose. Total left hemiplegia and hemi-anæsthesia. Cheyne-Stokes' respiration. No pus from trephine wound. Left cornea quite insensitive, but pupil acts very sluggishly to light. Temperature 101°. Right pupil also acts to light.

29th.—Right pupil dilated, and does not act to light. Right external strabismus. Right cornea anæsthetic.—11 P.M. Spasmodic twitchings in left hand and arm, lasting about two minutes at a time. The head also turns to the left. Stertorous breathing. Pulse 170; temperature 102·6°.

30th.—Died at 8 A.M. Temperature just before death 106°.

Necropsy, four hours after death.—Right hemisphere bathed in thick fetid pus, flattened, and very hyperæmic. About eight ounces of pus were collected. The base of the brain was also bathed in it. On the posterior surface of the right petrous bone was a small hole in the dura mater, admitting a fine probe. On stripping off the dura mater, a hole was found in the roof of the tympanum, through which a probe could be passed into the tympanum and out at the external meatus. For about half an inch all round the upper end of this unnatural foramen, the dura mater had been separated from the bone, so as to form a small abscess cavity (of old standing probably), which had apparently burst through the dura mater about the time of admission, and caused the cerebral symptoms. The brain on section was found quite healthy.

CROMER COTTAGE HOSPITAL.

A CASE OF CHRONIC EMPYEMA TREATED BY ESTLANDER'S METHOD; CURE; REMARKS.

(Under the care of Dr. H. MCCLURE.)

R. W——, aged twenty-one, was admitted on Nov. 29th, 1886. Family history fairly good. His present illness dates from a pleurisy six years ago. In November, 1883, he was in Cromer Cottage Hospital with an empyema of the left side, and under free drainage the discharge ceased. In April, 1885, pus was again issuing from the side; the point of exit was enlarged, free drainage secured, and the discharge again ceased. From this time he continued in indifferent health till May, 1886, when he was admitted to the Norwich Hospital with an open empyema. He left the hospital after a residence of two months, the discharge still continuing, and in September the side burst at another point higher up, so that now there were two openings, both giving exit to fetid pus. This state of matters continued up to the time of his admission in November.

On admission the patient was found to be fairly well nourished, but anæmic, with rather livid features and with most marked clubbing of the fingers, cough, and expectoration. The heart's impulse was half an inch below the nipple and an inch and a half to the right of the nipple line. The respiratory sounds over the right lung were normal; on the left side no true vesicular murmur was heard, except in a small space under the clavicle; dulness not absolute behind from half-way down the scapula. There were two openings in the chest wall, one below the eighth rib in the axillary line, the other in the sixth interspace, both discharging fetid pus freely. Both openings were enlarged, and a metal sound passed into the upper gave vent to a gush of very fetid pus, a loculated collection evidently having been tapped. Two large drainage tubes were then inserted.

The patient seemed to improve at first, the general health was better, and the discharge less, and, further, the upper opening closed; but at the end of three months there had been no material progress made. The discharge from the lower opening was still free; iodoform insufflations were used, keeping the discharge aseptic. There were also cough, lividity, and most marked clubbing of the fingers. As the side had been discharging pus for nearly a year, with a history of bad health for eighteen months, and there being not the slightest prospect of the empyema healing, resection of the ribs was determined on, and this was carried out on March 4th, 1887. Mr. Fenner kindly consented to help, and Mr. Mackintosh gave the A. C. E. mixture. An incision was made along the sixth rib, beginning about two inches outside the nipple line and reaching about four inches outwards. The periosteum was bared, and an incision made through it along the rib. About an inch of the rib in the middle of the incision was removed, being raised by a periosteum elevator and cut through with ordinary bone forceps. A further incision was then made from the inner point of the first for three inches downwards, the skin reflected, and the seventh rib bared, and a piece of about two inches and a quarter in length removed in the same way; the corresponding pieces of periosteum were also excised. The pleura was then snipped through with scissors, and was found to be almost an inch thick. There was now a large gaping hole in the chest wall of over an inch in diameter. The finger was introduced and the cavity thoroughly explored; it was found to reach backwards for three or four inches from the opening upwards, where it was roofed by the lung for about two inches, and downwards about three inches. It was bounded in front by the pericardium, through which the heart's pulsations were distinctly felt by the finger. The cavity throughout

Digitized by Google

seemed lined with a smooth and glistening membrane, and some adhesions in it were broken down by the finger. There was no troublesome bleeding until the pleura was cut through (only one vessel having to be tied), when there was a very profuse gush, which, however, was soon arrested by plugging the opening for a minute or two with carbolised wool. Some iodoform was then dusted into the cavity, a full-sized drainage tube introduced into the upper part of the wound, the edges of the wound brought together by a few silver sutures, a large pad of antiseptic wool adjusted, and the side firmly bandaged with a wide roller. The patient took the anæsthetic badly; there was considerable cough and vomiting, which rather embarrassed the proceedings; but the operation itself did not occupy more than a quarter of an hour. The after shock was rather alarming, but the patient had a comfortable night, a hypodermic injection of morphia having been given.

The after history was happily uneventful. There was no febrile disturbance (the thermometer on three occasions only registered as much as 100° F., the temperature at all other times being normal); the discharge, somewhat profuse for the first fortnight, steadily declined. The drainage tube was removed on April 20th, and a week later the discharge had practically ceased; there remained only a slight fungated small spot, which did not heal until two little pieces of necrosed rib came away.[1] He was discharged from the hospital on May 16th, and presented himself shortly afterwards with the wound quite healed. He had gained in weight and looked ruddy; his breathing was better, he said, than it had been for years, and clubbing of the fingers was not noticeable. The respiratory sounds were heard fairly well on the affected side, both before and behind, and there was distinct flattening of this side, more particularly just over the site of the operation, where there was a marked depression. The left side measured two inches and a half in circumference less than the right.

Remarks by Dr. MCCLURE.—Mr. Godlee's lectures on the surgical treatment of empyema, published in THE LANCET of Jan. 1886, suggested the treatment in the foregoing case. Of the seven cases operated on by Mr. Godlee only one had then healed. I think this case a very successful instance of the operation introduced by Estlander, and brought more especially to our notice by Mr. Godlee. I may say my patient was refused admission to a London hospital for disease of the chest by reason of the chronicity of the case. There is one point I should like to call attention to before concluding. For the first three or four days after the operation we had considerable hæmoptysis. What was the cause of this? I am inclined to think there must have been some expansion of the lung rupturing small vessels by a process of stretching. Besides, about a month after the operation, when changing the dressing, a violent fit of coughing seized the patient, and the drainage tube, which had been considerably shortened, was driven forcibly from the chest, followed by a gush of pus, though the discharge had been very slight for several days previously. Mr. Godlee, in his valuable lectures already referred to, says: "It is quite impossible for the lung to be distended by any inspiratory effort; this would be opposed to the law of physics." Be that as it may, I am inclined to think we had here another expansion of lung; at any rate, the patient's breathing seemed very much better after this, and the discharge rapidly ceased.

[1] The patient was shown at the May meeting of the Norwich Medico-Chirurgical Society.

PRIZES FOR PAMPHLETS ON HYGIENE.—The Spanish Society of Hygiene invites essays suitable for publication in the form of pamphlets or tracts, on the following topics: 1. The Hygiene of Work in Second Childhood. 2. Methods of obviating the Evil Effects produced on the Sight by faulty Conditions of Schools, and of the Methods of Instruction. A prize of £10 will be given for the best essay on each subject. Foreigners may compete, and the essays may be written in Spanish, French, Italian, Portuguese, or Latin. The length should be that of a 16-page pamphlet. The MSS. must not be signed, but must bear a motto, and accompanied by a sealed envelope bearing the same motto outside, and containing the name of the writer within. The essays must be addressed to "La Sociedad de Higiene, Madrid, No. 22, Madrid," before September 30th, 1887. The award will be announced at the opening of the academical session.

BRITISH MEDICAL ASSOCIATION.

FIFTY-FIFTH ANNUAL MEETING, HELD IN DUBLIN, 1887.

AT the second general meeting, on Aug. 3rd, Professor GAIRDNER delivered the address in Medicine, and, on the motion of Dr. LITTLE, seconded by Dr. BASTIAN, a vote of thanks to the giver of the address was carried with acclamation.

Sir THOMAS CRAWFORD then moved: "That, inasmuch as many members of the British Medical Association are aggrieved by the practice of those public institutions which limit the sphere of selection of their medical officers to candidates holding the higher qualifications of certain colleges, this Association shall adopt such measures as it may think best to induce the Medical Council to make it clear to the public that the higher registrable qualifications of the Colleges of Physicians and Surgeons of the United Kingdom are of equal value, or, if they are not, that the Medical Council will take steps to make them so, in order that the candidates holding such qualifications may be equally eligible for such appointments without reference to the nationality of the college from which their qualifications have been obtained." In these days of union he hoped they were all unionists. At all events they, as medical men, were unionists all over the country. Let it not be said any longer that those holding the qualifications of the Colleges of Surgeons and Physicians in Ireland could be excluded from getting positions in public institutions in England, but let them stand on an equal footing with their brethren in all parts of the kingdom. He would like to appeal to the meeting, and to ask whether the excellent address they had listened to was not testimony of the ability of Scotch physicians, and whether the splendid address they heard last night did not do credit to the Dublin University. The grievance they had was that certain English hospitals did not permit candidates holding Dublin and Scotch qualifications to compete for their positions. This was not altogether a doctor's question—it was a parent question also; and every man bringing up a child for the medical profession should consider it. He asked them to adopt the resolution not alone in the interest of their brethren practising in England, but in the interest of the public at large.

Sir CHARLES CAMERON seconded the resolution. He held that the Irish medical men were in no way inferior to the English, and he called on all laymen, as well as on members of the Association, to support the motion. The addresses they had listened to within the past few days showed that men of the highest attainments existed in Ireland; their colleges had sent forward men of the highest attainments, and it was too bad that those men should be tabooed in the way they had been. The Medical Act of 1858 abolished what must be regarded by every medical man as odious monopolies. It might be said that this was a lay grievance, and that they had not power to interfere, but they had the power to put moral pressure on.

Dr. HAUGHTON said the Medical Council had nothing to do with the higher qualification. They had to see that no person entered the profession who was not able to cure a broken leg or arm or who was not able to cure typhus fever. He had a friendly amendment, which Sir Thomas Crawford consented to accept, containing nothing but advice. It was, "That the Association is of opinion the diplomates of Irish and Scotch universities and corporations should possess the same privileges in respect of public appointments as are enjoyed by the diplomates of the other divisions of the United Kingdom."

Dr. WADDEL seconded the amendment, which he believed would effect all that Sir Thomas Crawford required.

Dr. SIBLEY said it was quite notorious that the degrees conferred by different universities represented a totally diverse standard. They were asked now to say that the qualifications were equal. He moved the previous question.

Dr. HOMER FITZPATRICK said he stood there as an Irishman, but he asserted also the rights of Englishmen and Scotchmen. He thought it would be very unwise for the

Digitized by Google

Association to agitate under every grievance that may occur. In any case, they had no power to interfere with private institutions maintained by voluntary subscriptions.

Sir WALTER FOSTER mentioned that the Council had twice refused to pass this motion. What was proposed to be done was to pass a resolution directing the various bodies in English hospitals and dispensaries to put the three qualifications to be had in the United Kingdom on a level. The qualifications were not of equal value. That of Edinburgh was not of the same standard as those of London and Dublin. He warned them against being turned aside by sentimental grievances, and against passing a resolution which would be merely waste paper.

Dr. STEWART (Clifden) read an advertisement which appeared in the English papers for a surgeon for the Liverpool Royal Infirmary, and which stated that the applicants for the position should possess the qualifications of the English universities. Although the hospitals were privately managed institutions, they were supported by the public, who desired the election of the best men. He asked Sir Walter Foster, would he to-morrow, if there were a vacancy in the hospital of Birmingham, stand up and say, "You are excluding men who are equal in every respect"?

Sir WALTER FOSTER rose to speak, but was ruled out of order.

The amendment was then carried by an overwhelming majority.

At the third general meeting on Aug. 4th, the address in Surgery was delivered by Professor EDWARD HAMILTON, Surgeon in Ordinary to the Lord-Lieutenant.

Sir GEORGE PORTER moved, "That the best thanks of the Association be given to Mr. Hamilton for his able and interesting address," which was seconded by Mr. WHEELHOUSE, and adopted with acclamation.

It was announced that Dr. Ward Cousins' prize of £20 had been awarded to Dr. Rentoul of Liverpool.

Dr. GRIMSHAW moved the adoption of the reports of the Scientific Grants Committee, which was seconded by Dr. BURNEY YEO, and adopted.

The report of the Collective Investigation Committee was also adopted, and the meeting adjourned.

At the fourth and concluding general meeting, on Aug. 5th, the address in Public Medicine was delivered by Dr. S. HAUGHTON.

Dr. THORNE THORNE moved, and Surgeon-General CORNISH seconded, a vote of thanks for the address, which was adopted.

Dr. E. WATERS moved, "That the cordial thanks of the members of the British Medical Association be given to the Provost and Senior Fellows of Trinity College, Dublin, and to the Senate of the Royal University of Ireland, for giving the use of their magnificent buildings for the meeting," which was seconded by Dr. KIDD and adopted.

Thanks were also passed to the President and members of the Dublin Branch to Surgeon-General Hassard and officers of the medical staff, and to various others, for what they had done in making the meeting so successful.

THE SECTIONS.

MEDICINE.

Aphasia.

At the meeting on Wednesday, Aug. 3rd, at 10.30 A.M., a discussion on Aphasia took place, which was opened by Professor CHARLTON BASTIAN. He began by expressing his belief that the functional activity of motor centres and of outgoing currents generally lie outside the sphere of mind. We become aware of movements which have been affected through sensory impressions of a kinæsthetic order, whose seat of registration is, as the author contends, in the so-called, but wrongly called, "motor region" of the cortex. The speaker dwelt upon the importance of distinguishing between memory and recollection, holding that the former may be active even where no consciousness of the process exists. This is the kind of revival of activity which principally occurs in kinæsthetic centres anterior to the repetition of movements, whether in speech, in writing, or other less specialised acts. Recollection always implies consciousness, and this more vivid form of revival occurs especially in auditory and visual centres. We have four kinds of word memory, two of which (the auditory and the visual) are especially active during silent thought, whilst the other two (viz, the glosso-kinæsthetic and the cheiro-kinæsthetic) become subconsciously revived during the expression of our thoughts either by speech or writing, the seat of their revival being in the so-called motor centres. Different kinds of amnesia are produced by lesions or defects in one or more of these centres for word memory, or it may be from mere defect in the commissures by which these word centres are brought into relation with one another. Sometimes a lesion in one of the commissures will lead to a speech defect which is clinically indistinguishable from a defect due to disease of one of the word centres, and this is one point upon which Dr. Bastian lays much stress. It is a point of much importance in reference to doctrines of localisation. In ordinary persons (that is, in those who are neither congenitally blind nor congenitally deaf) the four memories of words are mainly called into play in definite couples—viz., the auditory and the glosso-kinæsthetic revivals taking place during ordinary speech, and the visual, together with the cheiro-kinæsthetic revivals taking place during ordinary writing. In reading aloud, however, or in writing from dictation, the process is rather more complicated, three centres of word memory being necessarily active in each. It is certain that the visual and the auditory word centres must be brought into intimate relation with one another by means of two sets of commissurial fibres (visuo-auditory and audito-visual). It is possible that the parts of the general auditory and visual centres in relation with word impressions may be as distinctly defined as are the analogous parts of the kinæsthetic centre in relation with speech movements. It is certain there is one variety of amnesia in which the part of the auditory centre in relation with words is specially at fault (causing "word deafness"), and also that there is another variety in which the part of the visual centre in relation with words is specially at fault (causing "word blindness"). It is impossible to specify the precise situation of either of these word centres, though it is highly probable that they are near the posterior extremity of the Sylvian fissure, in, or in the immediate neighbourhood of, the anterior part of the occipital lobe. As to the situation of the other two word centres more definite statements can be made. The glosso-kinæsthetic centre is in Broca's convolution, while the cheiro-kinæsthetic seems to be located just above in the posterior part of the second frontal convolution. These two centres, which, following Ferrier, many regard as motor, Dr. Bastian considered to be sensory centres. The reasons in favour of this view he had elsewhere stated. Just as the auditory and visual word centres are connected by commissures, so is each of them connected with its functionally related kinæsthetic centre. Thus, we have the audito-kinæsthetic commissure connecting the auditory with the glosso-kinæsthetic centre; and the visuo-kinæsthetic commissure connecting the visual with the cheiro-kinæsthetic centres. If we employ the term "internuncial" for those fibres which pass outwards and downwards from the kinæsthetic centres of the cortex to the true motor centres in the medulla and spinal cord, then it becomes clear that for the proper study of speech defects it is needful to consider the results of lesions (*a*) in the different kinds of word centres, (*b*) in the different commissures by means of which these centres are connected with one another, (*c*) in certain internuncial fibres, and (*d*) in certain motor centres. The effects of lesions in these different situations was then considered. It was pointed out (1) that destruction of the auditory word centre would cause not only "word deafness," but also a complete aphasic condition; (2) that destruction of the visual word centre would cause not only "word blindness," but also agraphia, the lesion here, as in the previous case, being far away from the frontal convolutions; (3) that lesions of the commissures between the auditory and the visual centres give rise to extremely interesting forms of speech defect; (4) that lesions of any part of the commissures between the auditory and visual and the two kinæsthetic word centres would cause complete aphasia, indistinguishable clinically from that which would result from defects in these latter centres themselves—a doctrine which is of extreme importance from the point of view of cerebral localisation; (5) that the island of Reil lies over part of the course taken by these fibres, and hence we may account for the long-recognised fact that aphasia occurs with lesions in this situation; (6) that sub-cortical lesions of the internuncial fibres from Broca's convolution would produce a quite different kind of defect, in which, though the patient cannot speak, his mind is not in the least

Digitized by Google

affected, and he can communicate his thoughts freely by writing; (7) and that bulbar lesions produce an essentially different kind of defect so far as mind and speech are concerned, though the power to do writing may or may not be retained, according as the hand escapes or shares in the paralysis.

Professor GAIRDNER (Glasgow) said that having had an opportunity at the Liverpool meeting a few years ago of introducing a discussion on aphasia, he could hardly be expected to take a part in the present one without repeating himself to some extent. But as Dr. Bastian had just presented them with a new and individual view with respect to the whole subject, it was impossible to avoid indicating, in some degree, a feeling either favourable or adverse as regards what had been said. There was much to be said in favour of Dr. Bastian's views, especially as regards that very interesting and instructive part of them wherein he shows that in early infancy we are probably building up or evolving one set of centres, those required for spoken words; and then at a considerably later period quite another set of centres, those which are in operation for written language, through the eye and the hand. He would not follow Dr. Bastian throughout his exposition, but there was something attractive, and probably true, in this distinction. A good deal might be learned in relation to aphasia through the close observation of the first processes of speech in the infant; and the very remarkable study of M. Taine, published a few years ago, in which he gave details of experience, day by day almost, of the case of his own child, might prove a quarry for physiologists and pathologists to work in. Another way of studying the subject of aphasia was to take note of the rudiments of aphasic disability, sometimes even as regards particular words and phrases, which almost every man—at all events every man at all advanced in life—can usually find in himself. Several facts of this kind were taken notice of, as already adduced in the Liverpool discussion. But in true cases of pathological aphasia there were still many remarkable apparent anomalies to be brought into terms of law; and perhaps Dr. Bastian's views would help, as Dr. Gairdner thought they would, to explain such cases as that of the late Lord Denman, which, though mentioned at Liverpool, had by no means received sufficient attention, the peculiarity being that, although Lord Denman was all but completely aphasic as regards enunciation, he was apparently intact in his other faculties, and not only continued able to read largely in several languages, but employed his relatives to copy out what he read with particular approval, that it might be sent to his friends as his only possible way of maintaining a correspondence to which he was prompted by his warm and vivid interest in all current matters. A case which Dr. Gairdner intended to have presented at the discussion in Liverpool was interesting from a different point of view. It was that of a man paralysed on the right side and aphasic in all the ordinary senses of the word, both in the sense of word-blindness and word-deafness. This man, however, could play dominoes, and manifested in every way possible to him a complete command of intelligence as regards numbers. After a long time and many experiments of this kind, always with the same results, he discovered, almost by accident, that his own age was wrongly inscribed on the ticket attached to his bed. This led to further investigations, and it was then found that, although he was as impervious as ever to the mere verbal symbol for numbers, whether written or spoken, he could easily recognise Arabic numerals, and could with his left hand either write them in order, or indicate them when shown on the dominoes, *en vice versâ*.

SURGERY.

At the meeting on Wednesday, August 3rd, Sir GEORGE POLLOCK, F.R.C.S.I., on taking the chair as President of the Surgical Section, said that his first and pleasing duty was to return thanks for having been elected president of the Surgical Section of the British Medical Association. He considered it a very great compliment to preside over so many distinguished surgeons. He gave them a hearty welcome to Dublin, and hoped it would be a profitable meeting. Owing to a resolution that presidents of Sections were recommended not to give any formal address on the opening occasion, he would only say a few words. This was a wise rule, as papers of great value were often left over for want of room owing to the lengthy addresses delivered by the presidents. He referred to the great value of the papers brought before them, and hoped the discussions would prove interesting to them all.

Hernia.

Mr. MITCHELL BANKS (Liverpool) opened the discussion on the subject of the Radical Cure of Hernia. The operation which he adopted was removal of the sac and stitching the pillars of the ring. The operation was as simple as could be devised; and he gave statistics of 106 cases (thirty-eight of which were strangulated hernise) showing very satisfactory results. In children the wearing of a good truss in the majority of cases was quite sufficient without any operation. Patients should be watched for years; and he had very great doubts as to the pillars of the ring being closed thoroughly. There was in reality, in his opinion, no radical cure.—Mr. MACEWEN (Glasgow) described an operation by which he placed the sac of the hernia on the abdominal aspect of the inguinal ring, the details of the method having been published in the Annals of Surgery for August, 1886. Thirty-two cases had been operated on without a death. By an ingeniously constructed model he showed the steps of the operation and the method by which the needles were passed.—Mr. KHETLEY (London) referred to some cases treated by means of the injection of fluids—viz., concentrated decoction of bark. He believed that interference with the sac, except in skilled hands, was dangerous.

Mr. C. B. BALL (Dublin) read a paper on Twisting of the Sac in Radical Cure of Hernia, and described his method of torsion of the sac, which was grasped by a broad forceps, gradually twisting it, the finger at the same time freeing the neck. A catgut ligature was applied round the sac, tied, and cut off, sutures passed to prevent slipping, and the dressings painted over with a solution of salicylated potash. Of twenty-two cases operated upon by this method all recovered, scrotal abscess being the only bad result. He considered the wearing of a pad after the operation inadvisable. In large and bulky hernise torsion answered admirably, and in congenital hernise a modification of the operation was required. In one case of double hernia one operation cured the two.

Mr. BARKER (London) thought that the operation for radical cure was still *sub judice*. He only operated after trusses had failed. He described his operation, which was without risk. He had operated thirty-five times on twenty-nine individuals. He used silk ligature, hand twisted, and preferred it to catgut or kangaroo. Drainage was not necessary, nor a truss after the operation; on the contrary, he considered it injurious.

Mr. KENDAL FRANKS (Dublin) read a paper on the Radical Cure of Hernia. He also considered the wearing of a truss after operation injurious, as it had a tendency to cause reabsorption of the lymph effused. He made the skin incision on a higher level than the inguinal canal, and cleared the sac, which was excised, silver sutures being passed through the pillars of the ring. He was of opinion that closure of the inguinal canal was a very important procedure. The canal was closed by being glued to the aponeurosis of the external oblique.

Mr. MURPHY (Sunderland) read notes of a case in which a radical cure of hernia was performed by an unusual method. A man aged fifty, who wore a truss, suffered from symptoms of strangulation, and, dreading surgical interference, took the matter into his own hands. With a razor he made an incision down on the sac, cutting it off, and passing through the spermatic cord. He lost a good deal of blood, but made a good recovery. The pillars of the ring were brought together, and so far there had been no return of the rupture.

Mr. RABAGLIATI (Bradford) in a communication on the Radical Cure of Hernia, detailed three cases, all of which were successful, one having been operated on twice before by another practitioner. He removed the sac by the knife, and approximated the pillars of the ring by sutures.

Mr. MAYO ROBSON (Leeds), in a paper detailing twenty-five cases of radical cure of hernia, said in a good many of the cases strangulation had taken place, and in the remainder trusses were found to be useless. He used Wood's operation with strict antiseptic precautions, and the greater number appeared to be permanently cured. Two deaths occurred, both from acute bronchitis. He thought Mr. Macewen's operation promised great advantages.

Mr. THORNLEY STOKER (Dublin) read a communication on the Theory and Practice of Operation for the Radical Cure of Hernia. He referred specially to the radical cure

Digitized by Google

of inguinal hernia, and thought to allow silver sutures to remain permanently was unsound both in theory and practice. The closure of the inguinal walls was of great importance, and the lymph exuded was not due to the action of the sutures. In operating, the sac was exposed and carefully isolated, included in two catgut ligatures, and divided; torsion of the sac was advisable, and sutures through pillars tied button fashion over a leaden disc. As regarded artificial support after operation, he considered it usually as unnecessary, but in cases where some support is advisable Harrison's apparatus could be recommended; this consisted of a pelvic band and two thigh pieces, with perineal band, straps passing over the shoulder.

Mr. WALSHAM (London) said he had experience of about twenty cases by the radical cure, and preferred Mr. Banks' operation. The sac should be cleaned well up to the internal ring; he regarded this as important. The sutures he used were kangaroo. As regarded results, he had during the past six years only one case which was not radically cured. He did not recommend wearing a truss.

Mr. WARD COUSINS (Portsmouth) had operated on 120 cases, fifty for radical cure. He performed the operation in adults only when they were very bad cases, so that his principal patients were among children, who bore the operation well. He had no fatal result. Thirty of the cases were perfect cures; for the rest, sufficient time had not elapsed to form a positive opinion. He believed that trusses were very seldom properly applied. A pad applied after the operation (composed of an air-bag) had given satisfactory results.

Mr. HEUSTON (Dublin) read a paper on a Case of Strangulated Femoral Hernia, with Gangrenous Fallopian Tube and Ovary contained in the Sac. The patient, an unmarried lady, aged seventy, was operated on for strangulated hernia. Gimbernat's ligament was excised, the sac opened, and a loop of intestine returned; the sac also contained the right Fallopian tube and ovary, the former structure being in a gangrenous condition. The tube and ovary were removed, and the sac twisted, ligatured, and excised. The wound healed by the first intention, and the patient was out of bed on the sixteenth day. So far as he knew, there were only seven cases of femoral hernia of the kind described. The twisted neck of the sac he thought an important point. He used chromicised gut.

Mr. THOMSON (Dublin) thought the Section ought to be congratulated on the admirable discussion that had taken place. The different methods of treatment for the radical cure which had been brought forward showed that they had not arrived at a perfectly definite operation. He thought the improvement introduced by Mr. Ball to be the best method for treating hernia by the radical treatment. He had operated by this method on several occasions, and could recommend it strongly.

Professor KOCHER (Berne) had operated in seventy cases, and the method of operating he considered a very important consideration. It was important to distinguish between large and small herniæ. The suggestions of Messrs. Ball and Macewen he believed to be of great importance. He thought a good ligature of catgut or silver wire could be depended upon better than on the lymph effused.

Mr. WHEELER (Dublin) gave his own experience in operating for the radical cure of hernia, without entering into the discussion of the best methods of treatment. Where the sac was very large he excised it, and invariably used silk sutures, having an objection to silver. In children catgut was sufficient. In thirteen cases between the ages of nine months and eight years he had fairly satisfactory results; three were failures, but he had no fatal result. He used a pad, but not a truss, after the operation.

The PRESIDENT of the Section (Sir George Porter) thought operations of this kind were the safest they could employ.

Mr. MITCHELL BANKS, in replying, said the discussion had been carried on in the most harmonious manner. He thought one of the principal topics of the discussion was the removal of the sac. The torsion of the sac had proved to be of great service, and he hoped to use it and Mr. Macewen's method on the first opportunity. The simplest operation would be the one most extensively done. He advocated a truss, an elastic pad, and a light truss afterwards.

Spinal Abscess.

At the meeting on Thursday, Aug. 4th, Mr. LAFFAN (Cashel) read a note on the Treatment of Spinal Abscess. Cases which opened spontaneously or otherwise terminated in death. He recommended the plan suggested by Mr. Treves, of cutting down directly on the diseased bone, removing it, and tapping the abscess from the proximal end. Mr. Treves omitted the dorsal region, where Mr. Laffan wished to extend the operation, and also would not wait until signs of the abscess appeared. The pleura might be opened, but pneumothorax was less to be dreaded than that sinuses should form.—Mr. ILLINGWORTH (Lancashire) and Mr. FREMER deprecated the suggestion.—Mr. GIBNEY (N.Y.) said it was the rule in New York not to open abscesses early, as collections of pus were often absorbed, and it was the safest procedure to let them alone.

Abdominal Surgery.

Sir SPENCER WELLS read a paper on the Comparison of the Cæsarean Section with Porro's Operation. He had one case of each. In the Cæsarean section the fœtus, however, was only in the fifth month. The patient whose uterus and ovaries he removed died afterwards from cancer. The true Porro's operation was not the entire removal of the uterus. He wished to discuss the question in those cases where the child could not be removed by craniotomy or evisceration. Would it be preferable to use the Cæsarean section alone, or complete the operation by the removal of both ovaries and part of or the entire uterus?—Mr. IMLACH (Liverpool) thought Porro's operation an easier operation than that of Cæsarean section. He believed the time would come when the child could be removed in cases of pelvic obstruction without removal of the ovaries or uterus.—Sir SPENCER WELLS was surprised to hear Mr. Imlach say that Cæsarean section was the more difficult operation. He said that the enucleation of uterine fibroma was unsatisfactory, and he differed from Mr. Imlach in thinking it extremely hazardous. He concluded his remarks by referring to the electrical treatment then being discussed in another Section.

Mr. TAYLOR (Birmingham) brought forward a communication on a case of Cholecystotomy for Gall-stones, with remarks on the treatment of the blocking calculus. He detailed the case of a lady operated upon, in which four large stones were removed, but one was found to be wedged in the cystic duct, and had to be left. The operation was completed by securing the incision in the gall-bladder to the abdominal wall, leaving a drainage tube, and having the gall-bladder well syringed out twice daily. In a fortnight this impacted stone was removed, and the case did well.

Mr. H. ALLINGHAM'S (London) paper was entitled Inguinal Colotomy: its advantages over the Lumbar Operation, with special reference to a method for preventing Fæces passing below the Artificial Anus. He detailed the steps of his operation, which would require diagrams and more space than can be afforded to describe thoroughly. He pointed out the advantages of inguinal colotomy as compared with the lumbar operation, laying stress also on the position of the patient, which rendered the securing of the sigmoid flexure more easy.—Mr. BARKER (London) had performed three cases of inguinal colotomy, and preferred it to that in the loin. He did not consider it necessary to form a spur, as insisted on by Mr. Allingham, in order to conduct the fæces out of the abdominal cavity.—Mr. MAYO ROBSON (Leeds) said that the question of the difficulty of finding the colon was seldom referred to in books, but it existed very often. In cases of obstruction inguinal colotomy was not advisable.—Mr. LAFFAN mentioned Mr. Nunn's inflator. It was as easy to perform it as to extract a tooth.—Sir SPENCER WELLS thought opening the cæcum was sometimes to be preferred to left lumbar colotomy.—Mr. BALL (Dublin) said that occasionally a meso-cæcum was present, and then a wound of the peritoneum was necessary. An incision along the linea semilunaris offered many advantages. He exhibited his clamp for preventing the passage of fæces into the peritoneal cavity during the operation of colotomy.

Suture of the Patella.

Mr. HECTOR CAMERON (Glasgow) read a paper on Suture of the Patella, with a new suggestion dealing with a shortened rectus muscle. He believed that a permanently short ligamentous union was as good as union by bone. Almost all cases, however, where the union was a ligamentous one, were liable to tear. After wiring the patella he had his patients up in three weeks. He exposed the fragments, drilled opposite the centre of the fracture, used silver wire, twisted the ends and hammered them flat, and left them as a permanent clamp. Where the lower fracture was much smaller than the upper, he drilled from the lower surface. In his last

Digitized by Google

three cases there was no drainage of the joint. Shortening of the rectus muscle very often occurred; and if there were any uniting bands he cut them away, and in extreme cases incised the muscle, as suggested by Mr. Rutherford. These incisions were two in number, oblique, but did not entirely divide the muscle, the portion left on one side being incised on the other.—Mr. KEETLEY (London) had sutured eleven patellæ, and regarded the operation as a satisfactory one. No delay should take place in the operation. He tucked the ends of the wires against the fragments, as suggested by an American surgeon. The tissues outside the joint should be drained.—Mr. THORNLEY STOKER entered his protest against the very frequent use of suturing the patellæ. In recent cases he thought there was great danger in the operation.—Mr. MAYO ROBSON believed the operation to be surrounded by dangers in recent cases.—Mr. BARKER said that in the large metropolitan hospital to which he belonged suturing the patella was very rarely performed; they used a plaster-of-Paris case.—Mr. GOWANS (Newcastle) had no hesitation in performing the operation in both recent and chronic cases.—Mr. THOMPSON (Omagh) thought that in the immense majority of cases the plaster-of-Paris treatment, as used in University College Hospital, answered admirably.—Mr. MACEWEN said that under strict antiseptic precautions the operation was one which ought to succeed. In cases of shortened rectus V-shaped incisions were sometimes of advantage.—Mr. CAMERON, in replying, said excellent results for a time occurred when ordinary means were used, but they did not last, not being permanent. He did not recommend it to be a general operation.

Mr. PHILIPPS (London) read a paper on the Treatment of Ulcis Cruris by a New and Successful Method of Dr. Unna. He had used Dr. Unna's treatment in sore legs and could recommend the method. The affected parts are covered with fine cambric soaked with water, the cambric removed, and a tracing conveyed to paper. A glue composed of gelatine, oxide of zinc, and water was then applied to the healthy parts up to the limit of the sore. Over the sore a pad is placed, and around the leg a roller applied, traction being made from the healthy skin towards the ulcer. The dressing was removed in three or four days, the duration of the treatment lasting from four to six weeks. The results were very satisfactory.

Morbus Coxæ.

At the meeting on Friday, Aug. 5th, Mr. J. KELLOCK BARTON (Dublin) read a paper on the Operative Treatment of Morbus Coxæ. He described the steps of the operation—viz., a crucial incision was made over the trochanter, a small trephine used, and Volkmann's scoop applied, so as to remove the soft cancellous structure, more or less passing into suppuration. He used a drainage tube, and here was a practical point: this drainage ought to be maintained for a very considerable time. The operation gave immediate relief, and the results were very gratifying, and permanent also if drainage was kept up for at least two or three months, and the cavity of the bone occasionally washed out. As regarded excision of the hip joint, he considered it should be performed when the health of the patient failed, and when the possibility of death from exhaustion might cause anxiety, or the supervention of amyloid degeneration. The operation was done to save life and restore the use of the limb. When rest and other treatment had failed, then excision might be relied upon as eminently useful. It was surprising the reparation that occurred after excision. He alluded to a case where five inches below the trochanter had been removed, and yet this patient has only a shortening now of two and a quarter inches to two and a half inches, due to filling up of fibrous material. He exhibited a young girl from whose femur five inches had been taken away, and yet the shortening was only about two and a half inches.

Cachexia Strumipriva.

Professor KOCHER (Berne) read an interesting communication—viz., Cachexia Strumipriva and Myxœdema, which affections he considered identical. Cachexia strumipriva was due to destruction of the thyroid body. He had experimented on dogs and monkeys by removing the entire thyroid gland, and produced symptoms of cachexia strumipriva in those animals. As regarded the use of the thyroid gland, he did not know whether it had anything to do in the formation of blood-corpuscles, but he regarded it as useful in removing some excrementitious modifying something in the blood which might be otherwise injurious. He thought cachexia strumipriva was analogous to uræmia, the retention of some noxious portion of the blood acting on the nervous system.—Mr. GODLEE thought an important point was in the reference to complete and incomplete removal of the gland.—Mr. T. STOKER had removed the entire gland in two cases; the division of the isthmus of the gland was entirely useless except in checking the dyspnœa.—Mr. JESSOP (Leeds) said the communication was a most interesting one, and might have been read in either the Pathological, Physiological, or Surgical Sections of the Association. He performed tracheotomy for dyspnœa in one case, with ultimately good results on the tumour. He thought setons or sloughs formed by actual cautery of use, and incision of the isthmus for urgent dyspnœa.—Mr. GOWANS (Newcastle) asked Professor Kocher if cachexia strumipriva had as low a temperature as myxœdema, and if the pathology of the two diseases was similar.—Mr. G. STOKER (London) thought the function of the gland had not the power attributed to it.—Professor KOCHER, in reply, thought the gland was a secreting organ, and might be of service in removing something detrimental from the blood. If the smallest portion of the enlarged gland were left, the goitre recurred; the division of the isthmus was only to remove dyspnœa. He said the clinical appearances of both affections were the same—the same low temperature, scanty hair, and dry skin. No mucinoid substances formed, at least not in every case. He now commenced by excising one side of the goitre, which often stopped the dyspnœa of the other. On the opposite side he enucleated the pathological tissue.

Trephining in Cerebral Disease.

Mr. WHEELER'S (Dublin) paper was on Trephining in Mastoid and Tympanic Disease and Cerebral Abscess. He believed that the majority of operators did not select the proper site for the operation. Of sixteen cases which came under his notice of tympanic and mastoid disease with abscess of the temporo-sphenoidal lobe, the most usual site of cerebral disease, fourteen operated on recovered, and the remaining two died. The site he recommended was to bisect vertically the mastoid process, and in front of this he used the trephine on a level with the external auditory meatus, so as to reach the temporo-sphenoidal lobe. All his cases had recovered. Mr. Wheeler showed vertical sections of the head with and without the brain, to demonstrate that the lateral sinus was not touched, but the tympanum, dura mater, mastoid cells, and temporo-sphenoidal lobe.—Mr. BARKER (London) recommended as a site for the operation a point considerably above the meatus for trephining; he thought it a matter of great difficulty to diagnose an abscess of the temporo-sphenoidal lobe.—Dr. DRUMMOND (Newcastle-on-Tyne) detailed a case of cerebral abscess where aphasia was due to pressure. The pus having been drawn off, the patient recovered consciousness and power of speech.—Mr. JESSOP said the cerebral disease was due to the ear affection, and Mr. Wheeler's use of the trephine was the proper plan to meet the abscess in the brain.—Mr. PRATT (Dublin) considered the results of the operation most satisfactory. He had seen eight cases; the six operated on recovered, the remaining two died. He thought the lower operation the best for drainage purposes.

Litholapaxy in Boys.

Mr. WALSHAM (London), in his paper, Litholapaxy in Male Children, called attention to Bigelow's operation in children, and contrasted it with suprapubic or perineal lithotomy. He regarded the after-results in suprapubic lithotomy as being very serious. The objection in litholapaxy in children to the small size of the prostate and genitals was chimerical. The bladder was not very roomy, but many operators preferred a small surface, and it was expansile. As to the alleged narrowness of the urethra and its tendency to laceration, his answer was that it was not so narrow as was generally thought, especially when the meatus was excised. The extreme sensibility of the urethra was exaggerated, and in some cases he had operated without chloroform. He alluded to Surgeon-Major Keegan's experience in India, and laid down certain regulations in performing the operation.—Mr. W. COUSINS agreed with the author as to the suitability of the operation, especially for small stones.—Mr. CORLEY (Dublin) said that Surgeon-Major Keegan had informed him that he would operate on the youngest child if he could find an instrument small enough to use.

Tetanus

Mr. AUSTIN MELDON (Dublin) read a paper on the Treatment of Tetanus. He wished the members to test a

Digitized by Google

plan of treatment which in his hands had been singularly successful, and to place on record the results of treatment with different drugs in 937 cases of acute tetanus collected by him. In his first case, twenty years ago, he divided the nerve with only temporary relief, and he had since that time tried in succession Calabar bean, Indian hemp, curare, quinine, alcohol, and opium, with an invariably fatal result. Some years since he tried a combination of hyoscyamus, belladonna, and conium in a bad case, which recovered under this method, and since then several other cases, with satisfactory results. Of 17 cases in which these drugs were administered by him he had 13 recoveries and 4 deaths. The following statistics of 937 cases collected by the author of the paper are of interest:—In 370 cases treated by chloral, 83 recovered and 287 died; 135 treated by curare, 23 recovered and 102 died; 60 by nicotine, 3 recoveries, 57 deaths; 96 by opium, 4 recoveries, 92 deaths; 21 by conium, 3 recoveries, 18 deaths; 76 by cannabis indica, 12 recoveries, 64 deaths; 28 by bromides, 2 recoveries, 26 deaths; 103 by alcohol, 25 recoveries, 78 deaths; 17 by belladonna, conium, and hyoscyamus, 13 recoveries, 4 deaths; 41 by all other remedies, 17 recoveries, 24 deaths. All cases in which the first symptoms commenced later than the fifteenth day are excluded from this return.—Mr. JESSOP thought that such a successful result in cases of acute tetanus was unexceptionable, and he hoped Mr. Meldon would give fuller details.—Mr. WHEELER asked had nerve stretching been adopted?—Mr. MELDON said he had published several cases, and hoped to publish more; he had tried nerve stretching without permanent relief.

Treatment of Joint Disease.

Mr. SWAN (Dublin) read a communication on the Influence of Periosteal Section and Bone Drainage in Arresting certain Diseases of the Joints. He said that in children the joint most frequently attacked was the knee joint, and he selected this articulation as most commonly illustrative of those conditions of disease which might be combated by the method suggested. The cases suitable were as follows:—Extension of inflammation and its products from adjoining bones; the formation of abscess and its discharge into the joint; perforation of the encrusting cartilage, the sequel to carious or tuberculous bone; acute inflammation of the epiphysis and subsequent implication of the joint; the detachment of the periosteum from the extremities of bones, and the discharge of subperiosteal effusions into the joint. He described two cases as illustrative of the treatment recommended. In conclusion, he regarded counter-irritation in these cases as at best but a stereotyped empiricism, and rest a partially rational abstinence from treatment, but which would invariably terminate in the necessity of at least giving exit to products of disease under unfavourable conditions to excision, or to entire loss of the limb.—Mr. GIBNEY (New York) asked what fixation apparatus was used, and the time the treatment lasted. He had used igneo-puncture with good effects.—Mr. SWAN said rest was used after section of the bone until pain in the limb and passive movement of the joint had ceased. He thought bone drainage was better than igneo-puncture.—Mr. ILLINGWORTH (Lancashire) exhibited a new form of splint for the treatment of fractures into and in the vicinity of the elbow joint. He had found that fractures treated by the ordinary rectangular splint did not always give satisfactory results. He used a Gooch's splint, the hand lying prone, and in this way the axes of the arm, forearm, and hand were continuous.—Mr. FOY and Mr. HALL thought keeping the arm and forearm extended ought not to be recommended.

Mr. WARD COUSINS (Southsea) made some remarks on the treatment of retention of urine by aspiration through a capillary catheter, and exhibited the instrument. It was important to distend the urethra before and behind the stricture with oil when using his catheter.

Mr. STEELE (Clifton) gave a communication on the Radical Cure of Varicose Veins. He advocated removal of portions of the varicosed veins, a method which had proved satisfactory in his hands during the past ten years. He used Esmarch's bandage, and broke off the varicosed portion of the vein with forceps. The cases were perfectly cured in from four to six weeks by this method.

PHARMACOLOGY AND THERAPEUTICS.

This Section met in the Medical Theatre, under the presidency of Dr. Whitla (Belfast), and attracted a large and appreciative assembly. Amongst those present were Sir Andrew Clark, Sir Walter Foster, Mr. Wheelhouse, Professor Charteris, Professor Leech, Dr. Little, Professor Cuming, Professor Quinlan, Professor Walter Smith, and Dr. M'Hugh.

Dr. WHITLA began his address by alluding to the fact that this was the fourth year of the existence of the Section of Pharmacology and Therapeutics, which, under the presidency of his predecessors, Dr. Maclagan, Dr. Fraser, and Dr. Lauder Brunton, had passed successfully through its initial period. He deplored the unhappy position of pharmacology in this country owing to the mistaken interference of the Legislature, but he reminded the Section that the mere relief from harassing restrictions would be but a small step towards the accomplishment of great results, and urged the importance of a thorough testing and sifting at the bedside of the facts elicited by experimental research. The need of the day was not more additions to the already vast number of new remedies, but rather a more precise and scientific knowledge of how the remedies in our hands should be best utilised in the treatment of disease. It was discouraging to see how small a portion of current medical literature was devoted to therapeutics, for it should never be forgotten that successful treatment was the real *raison d'être* of medical science. Yet the fashion of the hour was to attach an undue importance to even the most superficial and fallacious physiological experiments, and to ignore the published results of clinical experience. What was needed was some machinery for bringing to a focus the accumulated experience of the profession upon the action and therapeutic value of the new drugs which the progress of pharmacology was continually putting into our hands. He thought the British Medical Association afforded the requisite machinery ready at hand, and he proposed that it should be utilised in the following manner: A portion of the journal of the Association might be set apart for the discussion of questions of therapeutics and placed under the management of a competent committee, who should from time to time select certain drugs and invite contributions tending to throw light upon their properties and uses. In this way the attention of the profession generally would be concentrated upon certain remedies, and the rich results of clinical experience would be gathered in. It would be seen that this method need not interfere with the working of the Collective Investigation of Disease Committee, of which the value had been chiefly seen in other fields than those of therapeutics. Much, no doubt, would depend upon the manner in which this suggestion should be carried out, and the responsibility of the Committee would be a serious one; but the great gain would be that many would be encouraged to watch and record the results of new remedies, and others would be induced to make known the accumulated experience of clinical observation, which otherwise they might never have thought of publishing. The suggested machinery might be utilised for another and similar purpose viz., for establishing a sort of popular control by the profession at large upon the national Pharmacopœia. That work reflected much honour upon its three distinguished editors, and the improvements recently introduced had been very great; but its tendency was constantly to lag behind the bulk of the profession in such important matters as therapeutics and posology. It was in such particulars that a *plébiscite* of the whole profession would be of most essential value. It would be possible to propose such queries as to whether a drug of doubtful value should continue to be retained, or some new claimant for attention admitted to the pages of the Pharmacopœia, and thus the general results of practical men might be brought to bear upon a matter that vitally affected the interests of the profession and the progress of medicine.

The President's address was listened to throughout with much attention, and warmly applauded at the close. The discussion which followed dealt with several questions of very vital interest to the profession, and may be expected to issue in important results.

Professor LEECH moved a resolution to the effect that a committee be appointed to collect information to be utilised in the production of the next edition of the Pharmacopœia. He said he was struck how little medical men relied upon the Pharmacopœia in their choice of drugs, and would give his hearty support to any plan which might be suggested whereby the feeling of the profession in general regarding the value of remedies could be ascertained.

Sir ANDREW CLARK characterised the President's address

Digitized by Google

as "lucid, able, earnest, practical, and important." He differed from Dr. Whitla, however, in one point—viz., as regards the value of the statistical method in arriving at the truth in questions of disease and treatment. No doubt the method was full of temptations to fallacy, but its great utility had been shown in the statistics regarding the various methods of treatment in acute rheumatism. Statistics had proved two things in this case: first, the immense value of the salicylates in the control of symptoms; and secondly, the necessity of continuing the treatment for a considerable period, even although all symptoms were allayed. He deplored the small share of attention given to practical therapeutics, of which no doubt the explanation was that many people did not believe in treatment. For his part, he did not hesitate to class himself among the believers in medicines. Disease was not a *thing* but a *state*, and just as certain things produced states of disease, so other things had power to remove them. He gave a striking case of the speedy relief of an urgent case of bronchial catarrh by hourly doses of one twenty-fifth of a grain of tartar emetic. He denied that the results of experiments upon animals could be at once transferred to the case of man, but nevertheless these experiments were of priceless value, chiefly for their suggestiveness. He cordially supported the proposals of the President.

Sir WALTER FOSTER concurred with Sir Andrew Clark regarding the great value of the President's address. He regarded it as a scandal that we did not devote our main efforts to the cure of disease. He thought scepticism upon the action of remedies was a most paralysing influence, and held that carelessness about treatment infallibly led to carelessness about diagnosis. We were being flooded with "eclectic" remedies from America and elsewhere, recommended only by chemists' circulars. No remedy ought to come before the profession without some scientific sanction. The Collective Investigation Committee had a scheme on hand which would cover many of the suggestions of the President. It was of great importance that the knowledge which was being slowly gathered by practitioners all over the country upon such a drug as strophanthus, for example, should be brought together and made available. The researches in pharmacology of Rutherford and Fraser would have been far more fruitful in their therapeutic applications if some machinery had been available for putting their conclusions to an extended test.

Professor QUINLAN (Dublin) briefly supported the resolution proposed by Dr. Leech.

Dr. LITTLE (Dublin) expressed himself as a strong believer in the efficacy of treatment. He deplored the small space given to the subject in the leading text-books. No doubt the subject was one of great difficulty, as we seldom found two cases so exactly alike as to afford proper material for a therapeutic experiment. He advised greater simplicity in the administration of drugs as a means of facilitating the observation of their results. He begged to move, "That a committee be formed to carry out the scheme sketched in the President's address."

This resolution superseded that suggested by Dr. Leech.

Professor CUMING (Belfast) seconded the resolution. He said he was, perhaps, open to the charge of not being a very enthusiastic therapeutist, but he felt safe in following the lead of such a chief among the *coryphæi* of medical science as Sir Andrew Clark. Some men, perhaps from the constitution of their minds, preferred to look upon disease chiefly from the etiological and pathological standpoint. It was impossible, however, not to be struck with the immense effect of drugs upon the human body.

The resolution was then put and carried unanimously.

Professor CHARTERIS proposed, "That the suggested committee be constituted as follows: Sir Andrew Clark, Dr. Little, Dr. Duffy, and the officers of the Section."

Mr. WHEELHOUSE expressed his confidence that the Council of the Association would carry out any suggestions emanating from that Section, and, if necessary, provide any [illegible] that might be necessary.

Professor WALTER SMITH (Dublin) supported the resolution, which was unanimously passed.

Dr. [illegible] then called upon Professor Unna of [illegible] to give a demonstration upon "Improvements in the [illegible] of the Skin."

[illegible] said he preferred to follow the *à priori* method, and to regard his subject rather from the physiological [illegible] The absorptive power of the skin was a very [illegible] the normal horny layer, forming a powerful bulwark against the absorption of remedies. In many cutaneous diseases the mode of application was of more importance than the selection of the drug. Certain remedies had a chemical, others a mechanical action. Of the former, caustic potash and soft soap were long used to soften the horny layer, but he regarded salicylic acid as preferable, because it was more powerful, and its action was more easily estimated than that of the other remedies. Of mechanical means of treatment he would mention the sprays. He had succeeded in curing eczema by the pure alcohol spray, and fungoid growths by a pure chloroform spray. The oleates seemed to act best when applied with the ether spray. The excretions of the skin were three in number: (1) water gas, or insensible perspiration; (2) fluids; (3) fatty matters. In the application of our remedies, we must consider whether we wished to promote absorption (thus necessarily limiting secretion), or, on the other hand, promote secretion (thus necessarily limiting absorption). The water bath restrained the fatty secretion, while the oily preparations applied to the skin restrained the watery secretions, and were, in reality, a species of clothing. We get the maximum of effect with medicaments applied to the skin under some impermeable substance. Powders, pastes, and gelatines gave absorption at its lowest limits. He then gave a practical demonstration of the application of some of his remedies, and exhibited some of the preparations made for him. One feature of these is the substitution of plasters for ointments, as being more cleanly and more easily handled.

Professor McCall Anderson, Mr. Malcolm Morris, Mr. H. G. Brooke (Manchester), and Professor Walter Smith took part in the discussion which followed.

At the meeting on Thursday, the first business was to hear a paper from Professor QUINLAN (Dublin), upon Strophanthus. The botanical characters, distribution, and varieties of this plant were fully described, and several interesting specimens were exhibited. Opinions had fluctuated as to which was the most active part of the plant, but the usual view was that the seeds were the most important. The natives of Central Africa, who used it as an arrow poison, obtained the active principle by crushing the seeds between stones. The preparation in common use was a tincture of the seeds, of a strength of 1 in 20. It had been said that this tincture should not be made into a mixture, but should be put separately into the vehicle on each occasion of use. The speaker had, however, regularly prescribed it in mixture without any ill effects. The active principle, strophanthine, had not been satisfactorily crystallised. It was a very active poison, $\frac{1}{30}$ gr. being sufficient to destroy a good-sized dog; $\frac{1}{200}$ gr. might be regarded as an average dose for man. Speaking of the therapeutics of this drug, Professor Quinlan regarded it as a valuable heart tonic. Its action was to strengthen rather than to stimulate the heart. He had found it of special service in prolonged typhoid fever, with feeble first sound and threatened cardiac failure. Its rapidity of action was extraordinary, the effect usually showing itself in fifteen minutes. In cardiac obstructive disease he had seen much relief follow its use. In fatty heart there was some benefit, but usually it was very fleeting. In anæmia with functional bruit it was useful. It did not lose its effect, nor did it (like digitalis) tend to accumulate in the system.

Professor LEECH (Manchester) followed with an address upon Sparteine, the active principle of common broom. He commented upon the extreme diversity of results reported by various experimenters upon this remedy. Some said it acted upon the brain, others upon the cord, others upon the heart and kidneys. He had carried out a series of researches with the view of settling some of these disputed points. One thing was certain about sparteine—it was a perfectly safe drug. He had himself taken five-grain doses without any unpleasant effect. He had found that it produced no effect upon either the brain or cord, but he was satisfied that it was a fairly powerful diuretic, though not so certain or potent as digitalis. In eight cardiac cases in which he had tried it, the increase in the quantity of urine had averaged ten or twelve ounces per day, and the stoppage in the use of the drug had been followed by the cessation of this increase. Like digitalis, it was useless in many advanced cases of heart disease, but he had known it to succeed where digitalis had failed. In acute kidney disease sparteine was useless, but it had a diuretic action in some chronic renal maladies. It had few disadvantages. Dyspeptic troubles were the only thing complained of, and these were not usual.

The PRESIDENT remarked that Professor Leech's observa-

Digitized by Google

tion filled an important gap. The results of experiments upon sparteine had been singularly conflicting, a fact which was probably largely owing to the very different doses employed by different observers.

The chief business of the day was then entered upon—viz., a discussion upon "The Therapeutics of the Uric Acid Diathesis." This was introduced by Dr. BURNEY YEO in an address which commanded the attention of a large auditory for nearly an hour. He said he would endeavour to confine himself to the practical aspects of the question. The pathology of the condition in which uric acid was present in excess in the organism was still doubtful. Murchison regarded the liver as primarily at fault, and with this view Professor Latham was disposed to concur. According to this theory, the essential condition present was the non-metabolism of glycosin into urea. Garrod, on the other hand, regarded the kidney as the active producer of uric acid. Ebstein placed its production in the muscles and marrow of bones. Frerichs held that the essential point was the perverted metabolism of albuminoid substances into urea. Bouchard denied that the presence of uric acid in excess was the chief feature in the morbid condition in question. One thing appeared certain—that the uric acid diathesis had its foundation in the imperfect metabolism of food, especially albuminoids. He (Dr. Yeo) would define it as "mainly a disturbed retrograde metamorphosis." Turning to therapeutics, he would point out that in all therapeutic questions three things had to be taken into account: 1, the pathogenic factor; 2, the constitutional factor; 3, the remedial factor. The two former were highly variable, and only the last had any claim to constancy. He would deal with the various remedies in detail. 1. Diet, regimen, and mode of life. There could be no doubt that, next to heredity, errors in eating and drinking were the most potent causes of the uric acid diathesis; but it was an error to assume that all gouty people had been intemperate. Ebstein regarded a tendency to obesity as a potent factor in the production of the condition, and advocated a dietary to check fat formation. He did not, however, entirely exclude fatty matters from the dietary. He allowed cabbage, peas, &c., but no turnips. He (Dr. Yeo) thought that no good results followed from prohibiting the moderate use of animal food. Senator advises a minimum of fats, and especially prohibits the yelk of egg. As regards alcohol, he thought it would be better for some persons, especially women, to abstain altogether; in others a moderate use of alcohol was not objectionable. Malt liquors and bad wines were to be carefully avoided. He regarded the cheap clarets in common use as particularly injurious. He held strongly that the *quality* rather than the *kind* of wine was the really important point. As a general rule, those wines were best which had a diuretic action. A small quantity of alkaline water might be advantageously added to the wine. Still Moselle was good, and was now much used. Exercise in moderation was important as tending to improve the general health, but it must be borne in mind that gout was very common in those who took a great deal of exercise, and that women, who led comparatively inactive lives, suffered far less than men. A warm, dry, equable climate was useful. All climatic conditions which interfered with the action of the skin were hurtful. He advised the regular use of considerable quantities of water, preferably hot water. Turning to drugs, colchicum had been much assailed of late years, but he had never observed the ill effects which some authorities attributed to its use. Garrod, Sir Thomas Watson and Graves had all borne witness to its value. He believed that its chief action was upon the liver. It had also sometimes a diuretic and diaphoretic action. As regarded the salicylates, he could not agree with Germain Sée that salicylate of soda was the best remedy which we possessed. The benzoates had been highly recommended, but he was not convinced of their utility. Guaiacum, in spite of the high commendation of Garrod, seemed to be generally neglected. Iodide of potash was very useful. Alkalies were in almost universal favour, but Dr. Latham did not think highly of them. There was a disposition at present to exalt unduly the merits of lithium, in comparison with soda and potash. He thought bicarbonate of potash was the most certain diuretic of the group. Magnesia and lime had been largely lost sight of, but the success attending the administration of the waters of Contrexéville (which contained large quantities of these salts) should direct our attention to them. He thought Bath was likely to be as useful as Contrexéville, and it was a much more attractive place. The mineral constituents of the waters at these two resorts were similar.

A discussion followed in which the following members took part: Dr. Latham (Cambridge), Dr. Myrtle (Harrogate), Dr. Kent Spender (Bath), Sir George Paget, and Dr. Kenny.

At 4.30 P.M. a special meeting of the Section was held to witness a demonstration by Mr. MALCOLM MORRIS of the Treatment of Ringworm of the Scalp. There was a crowded attendance, and Mr. Morris's able exposition was heard with much interest and attention.

At the meeting on Friday, August 5th, Dr. WHITLA (President) took the chair.

Dr. HARKIN (Belfast) read a paper upon the Treatment of Epistaxis. He believed that the liver was often at fault in this affection, which he regarded as the analogue of bleeding hæmorrhoids. He advised the administration of chlorate of potash, either alone or in combination with iron, and the application of a blister over the hepatic region. He had found chlorate of potash curative in some cases of an allied disorder—viz., the hæmorrhagic diathesis. It was difficult to say how this drug acted, but he thought highly of its value in all cases of sub-oxidation and altered metamorphosis. Some cases of epistaxis possibly arose from splenic congestion, and he had tried cupping over the spleen with success.

Dr. SANSOM (London) then gave a valuable address upon the Treatment of some forms of Aortic Disease. After a few remarks upon mitral disease, in which he said he had come to the conclusion that digitalis was our most efficient remedy in mitral regurgitation and convallaria in mitral stenosis, he gave an analysis of a large number of cases of aortic disease, from which he concluded that the two commonest causes of this form of cardiac affection were (*a*) rheumatism and (*b*) atheromatous degeneration. He had found these two causes about equally common. Aortic disease attained its maximum frequency in early adult life. In childhood, according to his observations, the mitral valve was affected in proportion to the aortic as 5 to 1. This accorded with general experience. He proposed to confine his remarks upon treatment strictly to one class of case—viz., aortic disease, arising from rheumatism; and he wished it to be distinctly understood that his observations did not refer to any other branch of the subject. He would divide rheumatic cases into two groups—(*a*) those in which there were no symptoms referred to the heart, and (*b*) those cases in which symptoms referable to the heart were present. As regards the former class, patients sometimes sought advice for the most diverse maladies. He related a case of a lad who consulted him for incontinence of urine, and in whom well-marked aortic disease with hypertrophy of the left ventricle was found to be present. In cases of aortic disease without cardiac symptoms, it might be laid down as an absolute rule that all agents which tended to increase the force of the ventricular systole were absolutely hurtful. Compensation being already perfect, such agents could only serve to disturb the equilibrium. Pain at the heart was an essential and early symptom in aortic disease, while it was well known that pain was not an essential symptom in mitral disease. The pain in aortic disease might attain the intensity of a true angina. Whether hypertrophy or dilatation should be the first to follow disease of the aortic valve was purely a question of nutrition. If nutrition were well maintained, hypertrophy would come first; if nutrition were imperfect, dilatation would precede. As regards the very important question of the administration of digitalis in aortic disease, medical opinion and experience had varied much from time to time. The present tendency was rather in favour of its administration, a view supported by so good an authority as Dr. Oliver of Newcastle-on-Tyne. While carefully guarding himself against an absolute expression of opinion, Dr. Sansom pointed out certain drawbacks to the use of digitalis—viz., (1) It may increase the distress and aggravate the symptoms present. In some of his cases where digitalis had had this effect he had seen great relief follow the administration of five-minim doses of tincture of aconite and the inhalation of nitrite of amyl. (2) Digitalis sometimes caused sickness. (3) In some cases where much temporary relief was obtained by its administration sudden death had followed, apparently as the result of its use. Yet, in spite of these dangers and drawbacks he believed that digitalis was sometimes of service in the *early* stage of aortic disease and for a *limited* time. If given in the same manner and for the same length of time as was usual in mitral disease, great evil would result.

Dr. COX (Dublin) followed with some remarks upon the Treatment of Acute Endocarditis and Pericarditis. He advo-

Digitized by Google

cated blistering over the heart, and the employment of perchloride of mercury, iodide of potassium, and turpentine.

Professor CHARTERIS (Glasgow), Vice-President of the Section, read a paper upon the Climatic Treatment of Consumption. He urged that patients should be recommended to remain away for two or three years. Hence, a place like Colorado, where invalids might find some occupation, had a great advantage over Davos. He related the particulars of a case of his in which severe hæmoptysis had come on during the voyage across the Atlantic. All remedies proved futile, but the hæmorrhage ceased upon arrival in New York. This patient was now doing well in Colorado. Another patient of his, after wintering at Davos, had subsequently died of rapid phthisis. He strongly urged the paramount necessity for consumptives adopting an out-door life, and quoted, with approval, the remark of Sydenham, that "quinine was not a more sure remedy for ague than was horseback exercise for consumption." He could not adopt Koch's views that the tubercle bacillus was the *vera causa* of the disease.

Dr. DRYSDALE (London) followed with some remarks upon the same subject. He believed in the curability of consumption, and had found a considerable number of instances of medical men who had recovered from the disease. He was formerly much in the habit of prescribing sea voyages, but now leaned to the high altitude treatment.

Dr. SYMONS ECCLES (London) then gave a demonstration of the manipulations employed by him in the application of Massage. The great interest felt in the subject was manifest from the crowded and attentive auditory which had assembled to hear Dr. Eccles. A couch was provided, and the various processes were thoroughly explained and illustrated upon the living subject. *Effleurage*, or stroking the muscles; *pétrissage*, or kneading the muscles; and *tapotage*, or tapping the muscles, were successively performed. Dr. Eccles employed lanoline for his hands, and gave his opinion that it was much to be preferred to vaseline or oily preparations. His cases would be subsequently published. He had used massage with great success in chronic dyspepsia, to the exclusion of all medicinal remedies; also in the treatment of stiff and painful joints. In reply to questions from the audience, Dr. Eccles said that massage was a very simple process, but that some persons were unable to perform it properly, simply from the want of the requisite manual dexterity. It might be performed two, three, or four times daily, according to the circumstances of the case. If the patient complained of fatigue after the process, it was an indication that it had been performed to excess. To guard against the possibility of rupturing a gastric ulcer or similar condition, a very careful diagnosis was indispensable before massage was performed. He related the case of a gentleman who was a cripple from a painful knee-joint affection, and who after six weeks' massage was able to walk two miles without fatigue or pain.

At the conclusion of Dr. Eccles' demonstration, the consideration of the Climatic Treatment of Phthisis was resumed.

Dr. MORLEY DOUGLAS (Sunderland) spoke highly of Las Palmas in Grand Canary as a health resort for consumptives. He thought it far superior to Madeira or Orotava, for the last of which somewhat extravagant claims had recently been put forward. The climate of Orotavo was not bracing, as had been alleged, but relaxing, there being excess of cloud. It had been described as a dry climate, but the mean daily range of temperature (so low as 5) was evidence of a humid atmosphere. Orotava was out of the range of the dry north-east trade wind, whereas Las Palmas came under its influence. This latter resort had a magnificent beach, fine drives, and good accommodation. Hygienic measures were being attended to. The water supply was much better than at Madeira. The results of treatment at Las Palmas has been very encouraging.—Mrs. Dr. GARRETT-ANDERSON made some observations on the general question. She strongly condemned sending advanced cases of consumption upon long sea voyages.

The proceedings of the Section soon afterwards concluded with the usual votes of thanks.

PATHOLOGY.

The Section met for the first time on Wednesday, Aug. 3rd, SAMUEL GORDON, M.D., presiding. In the unavoidable absence of the President, Dr. A. W. FOOT, Vice-President, took the chair, and opened the Section with a few introductory remarks.

Pathology of Empyema.

Dr. MARKHAM SKERRITT introduced the discussion on the above subject, which led to the following remarks.

Dr. RUSSELL was of opinion that in some cases resection of ribs was of great benefit. In cases treated early it was not usually necessary; in neglected cases it was of use. He considered it best to aspirate once or twice before making a free opening, so that the lung being relieved of pressure the parietal and pulmonary pleura may become adherent. Acute fetid empyema occasionally occurred on the left side. He considered that these cases began as diaphragmatic pleurisy, that the inflammation extended through the diaphragm, and that the fetor was due to the neighbourhood of the colon. This fetor was similar to that which occurs in abscesses adjacent to the bowel.

Dr. JACOB considered that the reason why collapse did not occur in many cases when the pleural cavity had been freely opened was because the greater part of the pleural cavity had been previously obliterated by adhesions. Why some effusions became purulent was not clear. He considered that empyemata were empyemata almost from the beginning, and that the serous stage was very short. In children pus had been found very soon after the initial rigor. He approved of preliminary aspiration before making a free incision through the chest wall.

Dr. ACLAND reviewed the various statements raised in the discussion. He was of opinion that the spontaneous evacuation of pus from the pleural cavity did not, as a rule, or in any large number of cases, take place in the direction of least resistance. He thought that a probable explanation of the fact that exit frequently occurred high up and anteriorly might be that the exact spot was determined by the position of the primary lesion which started formation of pus. He did not agree with the opinion that the admission of air into the pleural cavity was not generally followed by collapse of the lung. He instanced a case in which, when air was admitted into the pleural cavity in a previously healthy man, pneumothorax was at once produced. He thought that if the discussion resulted in some scientific investigations on this point the debate would not have been in vain.

Dr. FOOT considered that age and the general condition of the patient had more influence on the question whether the effusion was to become purulent or not than the nature of the local injury. In young people there is a tendency to rapid proliferation of leucocytes. He had noticed a curious tolerance of purulent, and intolerance of serous, effusions, some purulent effusions having lasted two years without marked symptoms.

Dr. MARKHAM SKERRITT, in reply, said that the formation of pus, according to the general opinion, was due to constitutional state. He used to aspirate as a preliminary step to opening the pleural cavity freely. He had now given up this mode of treatment, considering that it only causes a loss of time, and does not make it more probable that the pus left in the pleural cavity after the aspiration will be absorbed. Dr. Clifford Allbutt noticed that many cases of empyema went on for a considerable time without the occurrence of hectic fever, but that after aspiration hectic came on. He considered that there was little or no probability that aspiration will cure a case, and that it only allows more time for adhesions to form and bind down the lung more firmly.

Nature of Contagium in the Exanthemata.

Dr. G. THIN, in his paper on this subject, after explaining the reasons which had induced him to read only the part of his paper which had reference to scarlatina, went on to analyse the evidence which had been recently put before the profession by Mr. Power, Dr. Klein, and Dr. Edington. On examining the circumstances of the Hendon outbreak, he had satisfied himself by personal interviews with farmers that the cow disease at Hendon attacked two other herds supplying together nearly 500 families, and that no scarlatina was in these instances communicated. On these two farms there were three cases of poisoned fingers by the discharge from the sores of the udder, with the result of septic inflammation. In another case a milker scratched a pimple on his eyebrow, from which erysipelas spread over the head. Dr. Klein's investigations did not seem to him conclusive. He was inclined to attribute the symptoms and pathological changes in the animals observed by Dr. Klein to septic poisoning. He could not agree with Dr. Klein in considering that he had communicated to those

Digitized by Google

animals anything like scarlet fever. Dr. Klein's description of the cultivation characters of his streptococcus much resembled those given by Flugge of *Streptococcus pyogenes*, and by Dr. Edington of his *Streptococcus rubiginosus*. The most important point in Dr. Edington's research was, he thought, the absence of his bacillus from the desquamation scales till the fifteenth day, and its existence in the blood in the early stages before the other cocci known to be present in the blood and tissues were found. Dr. Thin acknowledged the value of Dr. Klein's and Dr. Edington's researches from the point of view of bacteriological research, but he did not consider that in either case the evidence was sufficient to induce us to consider it proved that in their respective organisms these investigators had found the veritable cause of the disease. He further urged the importance of comprehensive researches being at once made to determine whether animals were capable of developing scarlet fever, and to determine the number and nature of the organisms present in the blood in scarlatina. The cow disease at Hendon and the other farms might have been cow-pox, but he thought it more likely that it was the false cow-pox of Hering.

Professor MACFADYEAN said that the subject of Dr. Thin's paper was one of engrossing interest, and had more than an average interest for him, as his time was largely devoted to the study of diseases on the borderland of human and veterinary medicine. He had studied very carefully the history of the investigation into the Hendon outbreak, and he was not convinced that the udder disease was the cause of the scarlatina. The disease in the cows was of a very contagious character, and yet it appeared that instances of its prevalence in a herd were very rare, for, if it were not so, epidemics of scarlatina from this cause must be of every-day occurrence. He had made some investigations into eruptive diseases of the udders of cows before and since the Hendon outbreak, and he had seen numerous cases of an udder eruption which grew with the lesions described by Dr. Klein. It might be they were not identical, and certainly they had not caused scarlatina outbreaks. He thought that both Dr. Klein and Dr. Edington erred in not in the first place attempting to infect the calves and other animals with material taken direct from cases of human scarlatina. One calf he had fed with a very large quantity of desquamation, and another he had inoculated with blood from scarlatina patients, and yet these animals never developed a symptom of scarlatina.

Dr. SIMS WOODHEAD said he had been very much interested in Dr. Thin's paper. He thought that he had placed his finger on the weak spot in Dr. Klein's chain of evidence. In many cases it seemed to him that the pathognomonic features of scarlatina had been lost sight of, and similar conditions had been allowed to pass muster as the true scarlatina. After what they had heard of the resistance of the calf to both feeding and inoculation experiments, it did seem peculiar that Dr. Klein should only be able to produce any serious symptoms in parturient cows, or just those animals in which he had previously been able to produce certain pyæmic conditions. Dr. Edington had pointed out to him that his *Streptococcus rubiginosus* cultivated from scarlatinal blood was very like Dr. Klein's *streptococcus*, and Dr. Thin had, again, pointed out that they were very like the *Streptococcus pyogenes*. It should always be remembered that in the blood from scarlatinal patients there were numerous micro-organisms, and nothing was more probable than that the organisms above mentioned, which were so frequently associated with certain forms of inflammatory disease, should make their way into the blood, and so give rise to certain conditions when inoculated into a susceptible (parturient) cow. Dr. Woodhead was able to confirm what Dr. Thin had stated in regard to local abscess and lymphangitis following inoculation from a pustule.

Professor CROOKSHANK said that Dr. Thin's paper was of especial interest to him, as he had followed the researches in connexion with the contagium of scarlet fever very closely, and had recently published in THE LANCET a critique on the conflicting results obtained by Drs. Klein and Edington. The subject must be regarded as still *sub judice*. Dr. Edington's research was fairly complete, but still he was of opinion that an examination of the skin under other conditions and in health was most essential, and, indeed, might well have claimed attention from the very first. Dr. Klein's researches were also very elaborate, but the evidence adduced appeared to be in some particulars very weak. He instanced the omission of first proving that scarlatina could be communicated to a monkey by direct inoculation of blood or desquamation from a scarlatinal patient before concluding that the Wimbledon monkey died of scarlatina. Professor Crookshank concluded by saying that he hoped Dr. Klein would continue to prosecute his researches with redoubled energy, and strengthen his evidence in these particulars; but until then he thought he was fully justified in saying that Dr. Klein had so far only isolated a streptococcus which was intimately associated with a peculiar eruptive disease of the udders and teats of cattle, and that further evidence was necessary before it could be accepted as the veritable contagium of scarlatina.

Pathology of Bright's Disease.

Dr. W. R. THOMAS expressed an opinion that all cases of contracted kidney are originally caused by the passage through them of certain materials in the blood which have to be excreted, and which in their passage give rise to irritation, and ultimately cause the pathological changes. Some of these are introduced from without, as alcohol and lead; others are formed within the organism, as phosphates, urates, oxalates, &c. When alcohol is taken the chemist can prove its presence in the urine, showing that it or some of its constituents have been excreted. Lead can be readily found in the urine after it has been taken in. Patients who undergo too much exertion mentally, or who have had much mental worry, invariably pass a quantity of phosphates, which are most frequently found about midday—that is, after the bulk of the day's work has been done. Gouty patients pass urates and uric acid in large quantities for years often before actual renal disease occurs. Others who suffer from oxaluria pass also generally phosphates as well. Dr. Thomas felt confident, from examinations of a large number of cases, that all cases of contracted kidney are preceded by some one or other of these appearances, that albumen then appears, at first in small quantities. This gradually and steadily increases, and at last, if the disease is not cured by appropriate treatment, all the microscopical and other evidence, with symptoms of contracted kidney, show themselves.

Dr. ANDERSON thought that the disease spoken of by Dr. Thomas was in most instances not of a primary but secondary nature. The primary expression, in his opinion, was nervous, or existed possibly in the blood, producing a large excess of phosphates in the urine, and was accompanied by dyspepsia and inaction of the liver. Dr. Anderson thought that Dr. Thomas's paper was an exposition of what might be termed a temperance paper. It showed the necessity for temperance in the use of, if not of abstinence from, alcohol, and that the most frequent renal irritant was the quantity of alcohol daily introduced into the system.

Dr. WOODHEAD stated that he could not altogether agree with Dr. Thomas as to the pathology of granular contracted kidney. He had made post-mortem examination of numerous cases of alcoholic granular kidney, and of several cases of both lead poisoning and gouty kidney, and he must confess that by far the greater proportion of cases must come under the atrophic group. He considered that the most marked changes were in, and commenced in, the terminal vascular system, especially in and near the glomeruli. The walls of these vessels were altered. There were also changes in the glomerular epithelium, a loss of function, and then a loss of function in the convoluted tubules. He did not wish to say that the tubules might not also be more or less implicated in the first instance, but he did say that there was no such formation of fibrous tissue as had been often described. Excretion was carried on under great difficulties, and there was always a tendency for the disease to advance.

Actinomycosis Hominis.

Dr. MARKHAM SKERRITT read an abstract of a paper on the above subject. He had published a full account of his case in the *International Journal of Medical Sciences*. He illustrated his remarks with drawings, and with the liver in section, showing the character of the morbid growth *in situ*.

Professor CROOKSHANK said that he had elsewhere committed himself to the opinion that there were very possibly different forms of actinomycosis in animals, and, again, that the disease which had been described in this country as actinomycosis in man differed in the appearance of the fungus from the not so uncommon disease in animals. On the occasion of a paper by Dr. Acland at the Pathological Society

Digitized by Google

of London, Professor Crookshank drew attention to this very marked difference in the appearance of the fungus between Dr. Acland's case in man and the fungus (in his own specimens) from cattle. He drew attention to some sections of the bovine disease from different cases, and in all the peculiar club-shaped structures were present, and in these nothing approaching the network of mycelial filaments which characterised Dr. Acland's specimens could be seen. He understood that Dr. Skerritt's specimens gave the same characters as Dr. Acland's, while Dr. Israel's original case, on the other hand, gave the characteristic fungus as seen in the cow. He therefore looked forward with great interest to studying Dr. Skerritt's specimens, as some explanation of these differences was very necessary.

Dr. ACLAND said that he did not consider the disease which had been described was proved to be the same as that which occurs in cattle. It was seen that the clinical study of the two cases was very similar, with the exception that suppuration occurs much more frequently in man than in cattle. He did not think that the microscopical appearances shown were sufficient to show the identity of the two classes of cases. He believed, and gave evidence to support his belief, that a new disease had been described, due to a definite organism. There was at present no ground for believing that the cases which had occurred in man in England were due to infection from cattle.

Leucin and Tyrosin.

Dr. ANDERSON in 1879 read at Cambridge a thesis on this subject, in which occurred the following statement: "The presence of leucin and tyrosin in the urine of man, in the course of numerous diseases, shows that it is the function of the healthy liver to decompose them partly into urea, and to thereby prevent their undue accumulation within the system." Since 1879, many objections, of which the following are some, have been raised: "That leucin and tyrosin appear only in cases of acute atrophy, and in some few of the exanthamata; that they are never otherwise present in fresh, but only in putrefactive urine; that the instances of their appearance in fresh urine are apparent and not real; that they are stated by the author to be present in diseases having no apparent direct connexion with the liver. He replied to these objections. He pointed out how impossible it was for the blood as a whole, or even part, during health to be entirely free from them, and how much more liable it was in disease to be contaminated with them. He spoke of their dialysability, and of their presence in many perfectly fresh pathological fluids. He explained the methods employed for obtaining perfectly fresh urines, &c., and compared the behaviour of so-called pseudo-leucin and tyrosin with that of the true substances. Replying to those who ignorantly assert their non-clinical value, even if present, he showed the fallacy of these assertions. Replying to the objection that leucin and tyrosin are results of putrefactive change of peptones present in fresh urine, he asserts that, in most instances, the only peptonoids present in such urine are leucin and tyrosin, and that this was confirmed by repeated experiments.

(d) BACTERIOLOGICAL DEMONSTRATIONS.

The laboratory adjoining the physiological theatre, in which this Section held its meetings, Professor Crookshank exhibited a series of pathogenic and non-pathogenic microorganisms, both cultivations and preparations, under a large number of microscopes. The *Plasmodium malariæ* of Marchiafava and Celli and the semilunar bodies of Laveran, also found occasionally in the blood of malaria patients, were demonstrated as realities, and therefore, whether of any etiological importance or not, at least deserved attention as objects of interest. Now that King's College, London, has taken the lead in giving lectures and practical instruction in this department of pathology, as well as affording facilities for original research, and has set apart for this purpose a spacious and most completely equipped laboratory, medical men in this country will have a good opportunity for obtaining a practical acquaintance with the subject, and be able to form a more just estimate of the laborious researches which have elevated bacteriology into a distinct science. In the absence of such laboratories and places of instruction in this country, Professor Crookshank has done good service by having given on these occasions demonstrations of the practical side of one of the great questions of the day—the relation of bacteria to disease.

OBSTETRIC MEDICINE.

In this Section, which, if we may judge from the very large numbers who attended, was one of the most popular of the Dublin meeting, Dr. MACAN (Master of the Rotunda Hospital) presided, and gave a short and practical inaugural address, in which he drew attention to the value of a careful palpation of the uterus through the abdominal walls as well during labour as in the puerperal state. Further, he recommended that every woman should be examined two weeks before labour, so as to correct any malpresentation. Those who are thoroughly masters of the art of abdominal palpation will not need to make so many vaginal examinations—a point of considerable importance in the opinion of those who practise antiseptic midwifery. Dr. Macan then drew attention to the great importance of the "Dublin method" of treating the third stage of labour, and in a case-book of the Rotunda Hospital (1843), when Dr. George Johnson was master, he showed that the expression "placenta pressed off" was often found. He said that when Spiegelberg in 1855 visited the British Islands, the points that struck him most, from an obstetric point of view, were the Dublin treatment of the third stage of labour and the use of chloroform. He favours the Dublin method. Dr. Macan then dwelt on the great importance of the bimanual method of examination, and advocated the dorsal position, by which one can palpate the ovaries, the tubes, and make out the normal position of the uterus; and by this method, which is easier for both doctor and patient, one can examine both sides of the pelvis equally well. Further, in this position one can best wash out the uterus and apply antiseptic irrigations. In conclusion, Dr. Macan invited any of those present who wished to visit the Rotunda Hospital and see the practice.

Discussion on the Prevention of Puerperal Fever.

This discussion was opened by Dr. PLAYFAIR, who, after dwelling on the importance of the subject, said that a woman confined in a hospital where thorough antiseptic precautions were in force was as safe as anyone in the most luxurious practice. He wished specially to discuss this subject in connexion with private and domiciliary practice, where antiseptics are by no means in general use. Believing that puerperal septicæmia was analogous to that met with in surgical practice, he said the essence of antiseptic midwifery was—(1) to prevent the formation of the poison; (2) to prevent its absorption; and (3) to destroy it if absorbed. He advocated a thorough management of the third stage, and said the hand should not be removed from the abdomen for twenty minutes after the expulsion of the placenta; during this time gentle frictions are to be kept up, and ergot or ergotin (hypodermically) should be given. He advocated an examination of the perineum after labour, so that any lacerations could at once be closed with gut sutures, after a bichloride of mercury douche had been given. In such cases iodoform dusted over the parts night and morning was recommended. He gave his rules for the nurse (as in his "Midwifery") and the accoucheur. As carbolic lotion chafes the nurse's hands, he advocates the use of perchloride of mercury solution, but does not recommend it as a routine practice for syringing after labour. The vagina is to be syringed twice daily with a solution containing Condy's fluid. In conclusion, he dwelt on the importance of attending to the sanitary condition of the house in which a woman was to be confined.

Dr. ROBERT BARNES (London) drew attention to the importance of considering the condition of a patient before and immediately after delivery, which had a direct bearing on the predisposition to puerperal fever. Antiseptic are not the whole of the precautions to be taken. The peculiar condition of the patient must be attended to.

Dr. KIDD (Dublin), while believing in antiseptic measures, thought the disease prevailed at times in the form of an epidemic.

Dr. ATHILL (Dublin) said he was the first master of the Rotunda who used antiseptic precautions. He laid great importance on attending to the health of a woman before her confinement. In anæmic women he gave iron or arsenic, ergot being the vehicle for giving these drugs. He had no faith in the use of ergot in the third stage, but thought that if given for a short time before the labour with strychnine or tincture of nux vomica it was most valuable. It was no use in a single dose, as it took too long to be absorbed.

Dr. BYERS (Belfast) asked those who believed that puerperal fever might be epidemic or might arise in other

Digitized by Google

ways (cold) than from septic poisoning, how they explained the statistics of midwifery hospitals, where antiseptic measures were in force. He thought there was evidence to show that all cases were heterogenetic in their origin; and, in answer to the often-asked question, "How soon may a doctor resume practice who has himself been exposed to septic poison from a wound or scarlatina?" he said he believed that by baths, change of clothes, and thorough antiseptic washings of the hands, &c., the risk of carrying the poison was reduced to a minimum.

Dr. HUMISTON said he had just come from Germany, and had seen the obstetric physicians, after operating on the cadaver, wash and scrub their hands (nail-brush being used) for five minutes in a permanganate of potash solution, and then a second time in a basin with a corrosive sublimate solution, and immediately after take charge of a confinement, without any ill effects. He directed attention to the value of the urinometer in labour cases, a specific gravity below 1020 indicating, in his opinion, "breakers ahead."

Mr. LAWSON TAIT thought that by simplifying our ideas as to puerperal fever we were getting confused. He said there were two groups of cases—one class *systemic*, where we can do nothing, and the other *local*, where abdominal section and drainage are of great importance. It was hard, he said, to divide the groups of cases.

Dr. SLOAN (Glasgow) believed in the value of antiseptics, and directed attention to the importance of looking after the patient's surroundings, the value of fresh air (hence more puerperal fever in winter), of keeping the skin active (no sweating, and hence no chilling), of making few examinations, of a short second stage of labour, and of feeding the patients every two hours in the day and every four hours at night (hence no fainting). He had given up the routine use of the douche unless there is a necessity for it.

Dr. More Madden (Dublin), Dr. Cameron (Glasgow), Dr. Dill (Belfast), Dr. Molony (Arklow), Dr. Routh (London), Mrs. Garrett Anderson, Dr. Wallace, and the President also took part in the discussion, and Dr. Playfair replied.

Papers bearing on the Prevention and Treatment of Puerperal Fever were contributed by Dr. John W. Byers, Dr. More Madden, and by Dr. Robert Barnes.

Treatment of Fibroid Tumours of the Uterus by Electricity.

An interesting communication was made by Dr. Apostoli (Paris), with observations and complete statistics of all the cases so treated from July, 1882, to July, 1887, followed by a practical demonstration in the Rotunda Hospital by Dr. Apostoli himself. Owing to his inability to speak English, Dr. Apostoli's paper, which had been translated by his friend Dr. Woodham Webb, was read by Dr. W. Duncan, one of the secretaries of the Obstetric Section. In this communication Dr. Apostoli says it is five years since he adopted a proceeding which he defines as a galvano-chemical cauterisation of the uterus, vaginal, intra-uterine, or parenchymatous, and always monopolar. He points out that all the attempts made by his predecessors in the use of electricity were defective. The current of electricity was employed (1) in a vague and variable manner; (2) without dosage; (3) in a dose insignificant; (4) by a method always extra-uterine; and (5) by a method often dangerous. In 1882 Dr. Apostoli originated his new and rational way of using electricity, which he has since gone on modifying and improving. He claims to have supplanted the old method by a plan which is—1. Precise, by the introduction of new galvanometers of intensity, exact counters and measurers of the electric current. 2. Energetic. 3. Tolerable, in spite of the enormity of the doses, owing to the introduction of the wetted-clay electrode, which renders the cutaneous pole innocuous, and permits a current of signal medical intensity being transmitted through it easily and without injury. 4. Better localised. 5. Thoroughly under control. He applies to the diseased uterus a continuous galvanic current of an intensity and duration sufficient to produce the therapeutic effect required. This application is galvano-chemical cauterisation. 6. More scientifically exact. The positive pole is hæmostatic—anti-hæmorrhagic—in its action, sometimes instantly, or, again, gradually; it is the remedy, *par excellence*, in bleeding myomas; on the other hand, with the negative pole, we obtain a state of temporary congestion, without direct hæmostatic effect. It will render benefit in fibroids accompanied with amenorrhœa and dysmenorrhœa. He believes his method is—(1) Easy of application. (2) Simple. It is a skilful uterine therapeutic soundage. It needs a good galvanometer of intensity, a battery capable of yielding an adequate current of electricity, an inoffensive cutaneous electrode in wet potter's earth, an inattackable intra-uterine electrode in platinum, and a steel trocar for the galvano-punctures. (3) The current is mathematically dosable. (4) The seat of operation is optional. (5) It is of easy control. (6) It is antiseptic. (7) It is easily borne, as a rule. (8) It does not impose on the patients any forced exclusion. The positive pole is the remedy for bleeding, the negative for non-bleeding fibroids; but, further, if the negative pole is made *by puncture* to enter into the substance of the fibroid, it will ensure its diminution, and further, by a sort of *contrecoup*, will exert a hæmostatic action. Hence Dr. Apostoli gives these rules. Pole positive intra-uterine for the restraining of hæmorrhage; pole negative intra-uterine for non-bleeding tumours; while the indications for galvano-puncture are twofold—(1) as a matter of necessity, owing to uterine atresia, or where a sound, owing to displacement of the uterus, cannot be introduced; (2) by preference, if the punctures can be combined with intra-uterine cauterisation, so that one can expedite and make sure of effects which, with the cauterisations, only would be slower and more imperfect. Dr. Apostoli gives the following directions for galvano-puncture: 1. Antiseptic vaginal irrigation before and after each operation. 2. The puncturing instrument should be a small steel trocar or needle, and the punctures should be shallow, not deeper than 1-2 centimetres. 3. The puncture should be made in the most prominent part of the fibroid, if possible in the posterior cul-de-sac. 4. No speculum should be used. 5. The seat of any pulsation should be ascertained, so as to avoid wounding any vessels. 6. If there is any unusual hæmorrhage the vagina should be dilated with an expanding speculum, and, if necessary, pressure forceps should be put on the bleeding point. Dr. Apostoli claims that, as a result of this plan, every fibroid tumour will undergo a reduction appreciable by touch, and demonstrable by internal measurement. The reduction of the size of a tumour is generally associated with an accumulation of subcutaneous adipose tissue on the abdominal walls. Further, the regression of the tumour goes on after treatment has been suspended, it becomes liberated from its local attachments, and it tends to become more sub peritoneal and pediculated Again, from a clinical point of view, Dr. Apostoli asserts the results are not less striking. He says that ninety-five times out of a hundred all the miseries constituting the fibroidal condition are suppressed, such as hæmorrhages, the troubles of menstruation, dysmenorrhœa, amenorrhœa, nervous disturbances, the direct pains in the growth itself, and from mechanical pressure and the harassing series of reflex actions. Dr. Apostoli has, in the five years from July, 1882, to July, 1887, made, either privately or at his clinique, as many as 5,201 applications of continuous galvanic currents for most of the maladies included in the gynæcological nosology, which he thus enumerates in the following order:—(1) Fibroids of the uterus—polypi; (2) entire or partial hypertrophies of the uterus; (3) subinvolutions; (4) acute and chronic metritis and endometritis; (5) ulcerations of the neck of the uterus; (6) periuterine inflammations (perimetritis, parametritis, cellulitis, phlegmons); (7) ovarialgia; (8) ovaritis and periovaritis; (9) salpingitis; (10) ovarian and tubular cysts at an early age; (11) atresia; (12) hæmatocele. These 5,201 operations (during a period of five years) were made upon 403 patients. Of these he lost only two; in one he says he did not recognise the existence of a suppurating ovarian cyst which ended in death from peritonitis, in the other death was due to a puncture made too deeply. From July, 1882, to July, 1887, he has had under his care 278 patients with fibroids or hypertrophy of the uterus in some manifest degree, upon whom he has used 4246 applications of the continued current of electricity. He does not wish to convey the impression that all have been cured, but he affirms that when there has been no negligence, and where his advice has been fully acted on, 95 times out of 100 permanent benefit has been acknowledged. Among the patients who had not the will to let Dr. Apostoli finish what he had begun, and whose impatience led them voluntarily to seek removal of their tumours by excision, seven put themselves into the hands of six most eminent surgeons, and not one recovered from the operation. It is of great importance that this new method of treatment should be brought before the notice of

Digitized by Google

the profession, and hence a full *resumé* of Dr. Apostoli's paper is given.

In the subsequent discussion Dr. PLAYFAIR (London) said Dr. Apostoli's paper was a model of accurate record; his opinion was that this new plan of treating fibroids by electricity had in it great possibilities. He had employed it in his own practice, after having visited Dr. Apostoli in Paris, and from his own experience he was certain of its hæmostatic properties. It was not, however, he thought, a simple method, and needed technical knowledge.—Sir SPENCER WELLS was struck with the improvement in the general health of the woman treated in this way, and with what was a very strange feature, the deposit of fat in the abdominal walls as the tumour disappeared. One of his own patients went to Dr. Apostoli with a fixed uterus, and after thirteen or fourteen applications she returned in much better health, and with an almost mobile uterus.—Dr. STEAVENSON (London) said what we were specially indebted to Dr. Apostoli for was that he has shown stronger currents can be used, and his potter's clay electrode was entirely new. He showed the instruments he had recommended.—Dr. SKENE KEITH (Edinburgh) and Dr. W. DUNCAN (London) both spoke in favour of the method, the former remarking on the great improvement in health that the patients seemed to undergo.—Dr. MACAN (Dublin) said the plan of treatment was, at any rate, expensive, and applicable to patients with long purses.

Owing to the kindness of Dr. Macan (Master of the Rotunda Hospital) many gentlemen had an opportunity of seeing Dr. Apostoli demonstrate his method of treatment in a practical way. Our own impression is that, although Dr. Apostoli may, like every enthusiast, over-estimate the power of electricity in gynæcology, yet that there are many conditions in which this line of treatment may prove most successful. Dr. Apostoli has now brought it fully and fairly before the gynæcologists of this country, and it is only just to him that they should (and we know some have done so already) give it an honest trial and report their experience.

Management of Anterior and Posterior Displacements of the Uterus.

In opening the discussion on this subject, Dr. HALLIDAY CROOM (Edinburgh) said that he quite realised the responsibility he incurred in endeavouring to lay down definite lines of treatment in such a vexed question as that of anterior and posterior displacements of the uterus. He divided them into two great classes—(1) those occurring in nulliparous women; and (2) those occurring in parous women. In the first class he believed the displacements were entirely congenital, due either to non-development or deformity, and he strongly recommended that mechanical interference should, as a general rule, be avoided, both in anterior and posterior displacements. He believed that in the majority of cases they gave rise to no symptoms, and when symptoms of dysmenorrhœa or pelvic distress were present, concurrently with them these symptoms were due to some affection of the uterine annexa, for which mechanical treatment was utterly unavailing. He did not deny that in some exceptional cases mechanical treatment was necessary, but these cases were so rare as not to affect the general fact. With regard to parous women, the case, he thought, was distinctly different. In the many symptoms arising from anterior displacements were due to some inflammatory process in or around the uterus, and the treatment should be directed to the removal of those inflammatory products, and not mechanically to the displacement of the uterus. With regard to posterior displacements in parous women, Dr. Croom thought that a distinction ought to be drawn. They, as a rule, were brought about mechanically, and, speaking generally, were the only forms of uterine displacement that required mechanical treatment. In the case of retroversion, if no adhesions were present, he believed that the uterus ought to be accurately replaced bimanually without the use of the sound, and retained in position by a Hodge pessary, or some other modification of that instrument. In retroflexion the Hodge pessary seemed to him inapplicable, and he believed that, as a rule, endeavours at replacement should be employed with care, and the uterus retained *in situ* with an ordinary ring pessary. In conclusion, he pointed out that there were some cases which required exceptional treatment, but in the main he advocated mechanical treatment for posterior flexions and versions only in parous women. Dr. [illegible] said no pessary in his opinion was curative. He regarded anteflexion as an exaggerated natural condition, and thought pessaries for this useless; but in posterior displacements he advocated the use of these supports as an aid, but not a means for cure. He did not use stems.—Dr. ROBERT BARNES (London) said pessaries were useful if there were no adhesions. He looked upon the ring pessary with horror, as it weakens the natural support and does nothing towards cure. He was sure a proper pessary would cure in time.—Dr. W. DUNCAN (London) thought the vast majority of flexions were not to be treated, as a flexion *per se* cannot cause trouble. The trouble in anteflexion was due not to any stenosis, but to the state of the endometrium. He advocated the use of the bimanual method instead of the use of the sound, and thought that in the majority of cases of flexion no mechanical treatment was necessary.—Dr. WALLACE had seen hundreds of cases of displaced uteri cured by pessaries, but the morbid condition was also cured, and no pessaries were of use till these conditions were made right.—Dr. ROUTH (London) thought the sound should be used, and believed in stem pessaries, if those who used them would see that the instrument went just beyond the flexion, and would keep the patient quiet in bed for some time after introducing the stem pessary.—Dr. KIDD (Dublin) had not lost faith in pessaries, and said in some cases of displaced painful ovaries he had found them most advantageous.—Dr. CAMERON said in Glasgow they had some very successful cases of displaced uteri treated by the "Alexander Adams" operation of shortening the round ligaments.—Dr. W. J. SMYLY (Dublin) drew attention to the importance of subinvolution of the ligaments as a cause of displacements. He showed that the best way to replace a uterus was by the fingers, and that until it was placed in proper position the pessary was of no use. He explained the action of the pessary, and thought cases were cured by it. In reference to cases of backward displacement, he pointed out that Schroeder had used gentle vaginal massage with good effect when adhesions existed.—The PRESIDENT (Dr. Macan) having called attention to the normal position of the uterus, said that his practice was to bring forward the uterus thoroughly, and then to insert a pessary to keep the cervix back. He had had exceedingly good results by such methods.

Dr. MORE MADDEN read a paper on the Treatment of some forms of Sterility, in which he advocated the forcible stretching of the cervix and catheterisation of the Fallopian tubes.

Dr. CAMERON read a paper on the Pathology of Abortion, and exhibited several very interesting specimens illustrative of this condition.—In the discussion on this paper, Mr. LAWSON TAIT said his practice at the Midland Hospital for Women in Birmingham was, in cases where from the history he suspected an abortion, to give ergot with bromide or chlorate of potassium for a week, and then, if there was still hæmorrhage, he introduced his alligator forceps, and cleared out the contents of the uterus.

Dr. W. J. SMYLY (Dublin) read a paper on the Diagnosis and Treatment of Diseases of the Endometrium, in which he showed the value of the curette, as well for diagnosis as for treatment.

Dr. ROBERT BARNES read a paper on the Theory and Treatment of Placenta Prævia, in which his well-known views were brought forward.—Dr. MURPHY (Sunderland) drew attention to the importance in such cases of bringing on premature labour, a view with which Dr. Kidd agreed.

Dr. O'CALLAGHAN read notes on a Month's Abdominal Sections, by Mr. Lawson Tait. Mr. Tait had allowed him to see his hospital and private practice for one month. During this period he saw Mr. Tait do thirty-five abdominal sections, all ending in recovery except one. The fatal case was one in which Mr. Tait removed one set of appendages, he having removed the other some time previously. Dr. O'Callaghan gave a *résumé* of the cases, and said Mr. Tait used no antiseptics, but relied on strict cleanliness and dry dressings.—Having been asked to speak, Mr. LAWSON TAIT said he made no selection of his cases; he never refused to operate on a case in his life. He drew attention to a case in which he had opened and drained the abdomen for suppurative peritonitis occurring during pregnancy. The case ended in complete recovery. He mentioned that one case recorded by Dr. O'Callaghan, in which he had removed the ovaries, was of extreme interest. He had seen six such cases, and five of these came from the Vale of Taunton. The history of these cases was as follows. A girl sixteen or seventeen years of age is seized with profuse hæmorrhage at each

Digitized by Google

period, lasting often for fourteen or fifteen days. In such cases he found that all medicines failed, and the ovaries, when removed, were three times as large as normal, and had cysts. Mr. Frederick was at present examining the specimens. In the case recorded, twenty-four hours after the operation, the hæmorrhage ceased, and there had been no recurrence for a month. In these cases the ovaries, and they alone, caused the menorrhagia.—Dr. LAWRENCE having drawn attention to cases of puerperal fever with distended abdomen, Mr. Tait said his opinion was that no cases of puerperal peritonitis should be allowed to die without abdominal section.—Dr. W. DUNCAN spoke of the good results he had seen from the administration of drachm doses of bromide of potassium in the metrorrhagia of young girls.

Dr. A. D. SINCLAIR read a paper on Manual Dilatation as a means of Inducing Premature Labour.

PUBLIC MEDICINE.

This Section, held under the presidency of Sir THOMAS CRAWFORD, M.D., K.C.B., was well occupied throughout its sittings with an abundance of good papers. The principal ones were grouped under two special headings. The first raised the question of the best methods for dealing with the insanitary property now occupied by artisans and labourers, the subject being introduced by Sir Charles Cameron and Dr. Stopford Taylor. The latter drew attention to the circumstances which both in the past and in the present day had led to the dense aggregation of houses on area; and he referred to the action which it had become imperative to undertake in the city of Liverpool in order to deal with the grave evils which had arisen. Sir Charles Cameron also gave some account of the remedial measures which had been adopted in Dublin; but it is quite evident, both from the state of the existing buildings occupied by the poor and from the number of one- and two-storeyed houses which it has been found practical to erect in Dublin under recent works of improvement, that this question of open space about houses is by no means so pressing in Ireland as it is in our English towns and cities. In this country we also have to meet the tendency to imitate, in comparatively sparsely-populated districts, that which is done in the towns, the evils culminating in the erection in our northern counties of a class of house which is known as back-to-back. Under this system there is absolutely no open space to the rear of houses, and though under the conditions of their present occupancy it may be difficult to prove actual injury to health in individual cases, yet it must be admitted that the practice is in violation of one of the first principles of health. In his opening address to the Section, Sir Thomas Crawford had given a most gloomy account of the condition of recruits drawn from town populations as opposed to those coming from the rural areas, the inferiority of the town recruits being especially marked in the insufficient capacity of chest, the loss and decay of teeth, and the diminutive stature; and as the result of a lengthened debate, in which Dr. Grimshaw, the Registrar-General of Ireland, and Dr. Thorne Thorne of the English Local Government Board, took part, a resolution was proposed by Dr. Tatham, and seconded by Dr. John William Moore, the two honorary secretaries, to the effect that this Section, having regard to the great importance of securing through-ventilation of dwelling-houses, desired to express its emphatic condemnation of the system of building houses back to back, and to urge that measures should be taken under legislative enactment to secure a minimum amount of open space to the front and the rear of all newly constructed dwelling houses. The second main topic of debate related to the influence of modern preventive measures on the prevalence of infective diseases. The first group of papers dealt largely with the effects of modern sanitary laws, their value and defects being indicated and illustrated by the several readers of papers. As the result of the discussion which ensued, it would appear that, defective as our English system may appear in the eyes of those who are conversant with all its faults, the general sanitary administration of the sister island is infinitely more imperfect, and calls for improvement and reorganisation. As regards foreign diseases, a paper was read by Dr. Thorne Thorne, one of the vice-presidents, on the subject of Sea-borne Cholera; the preventive system adopted in this country being compared with the restrictive system of quarantine to which so many governments on the Continent of Europe still cling. The details of the epidemic of 1884-87 were brought forward to illustrate the more prominent facts, which went to show how utterly cholera had in its march ignored the lines of quarantine which had been raised to bar its progress, and how truly remunerative the expenditure incurred in this country had been; our alternative system involving true measures of prevention, which had saved a vast amount of life and spared us from much suffering and distress. In connexion with this system of disease prevention two other papers deserve mention. One, by the Registrar-General of Ireland, dealt with Class Mortality Statistics; Dr. Grimshaw showing the valuable indications which had followed on the classification of the population into social classes for the purposes of death registration. The other was by Dr. Churton of Leeds, the subject being the Registration of Plumbers, much on the lines so well undertaken by the Plumbers' Company in the City of London. On the value of this system the Section were unanimously agreed, and in the form of a resolution they expressed their conviction of the absolute necessity of the adoption of such a system under the auspices of a competent body in each portion of the United Kingdom. Amongst the incidental subjects brought under the notice of the Section was that of Burial Reform, by Mr. Frederick W. Lowndes of Liverpool, who strongly advocated cremation. The general feeling of the Section was distinctly condemnatory of the present system of burial, and also in favour of the alternative suggested in so far as health considerations went. But it seemed clear that a majority did not hold that the safeguards suggested against crime, and especially against poisoning, were sufficient to do away with a serious evil. Thus, inquests in all cases of cremation would certainly be prohibitory as a rule, and ordinary proofs as to death having been due to natural causes, even if based on post-mortem examinations carried out without the aid of special experts, would in many cases be quite valueless. Under these circumstances, the general feeling of the Section was that improvement in the disposal of the dead being at once called for, the change could best be effected in the direction of the system known as earth-to-earth burial. One subject was not dealt with in the Section, and this although some of the sanitary circumstances of Dublin came under discussion; and it is probable that the lavish hospitality displayed by the Irish capital had closed the mouths of all as to the state of the Liffey. But many whose pleasure or duty called them along the quays bounding that stream at low water and under the glorious sun, which characterised the week of the meetings, muttered silently against the enforced inhalation of the foulest and most fetid air which can well be found in any city in the world, and one of the best hopes they could express for the well-being of their courteous hosts and Irish fellow-countrymen was that the Corporation of Dublin would no longer delay dealing with an evil which has reached a stupendous magnitude.

THE ANNUAL MUSEUM.

The twentieth annual Museum was held in the Anatomical Department of the Medical School, Trinity College. It was arranged in four sections—viz.: 1. Food and Drugs. 2. Recent Books, Instruments, and Appliances. 3. Anatomical and Pathological Specimens and Drawings, Microscopes, and Microscopical Preparations. 4. Hygienic and Sanitary Appliances. In the Food and Drug Section there were thirty-five exhibits, seven of which were Irish. Moore (Belfast) had extracts of meat; L. Hoff, extract of malt; Harrington (Cork), materia medica cabinets and various pharmaceutical preparations; Burroughs, Wellcome, and Co. showed Wyeth's tablets; Feltoe and Sons, lime juice; while Evans, Sons, and Co., of Liverpool, showed an extensive collection of their well-known preparations, which include fluid extracts, concentrated liquors and waters, and coated tasteless pills. Among the Dublin exhibitors in Section 2 were Messrs. Boileau and Boyd, Corcoran and Sons, Fannin and Co., and Prescott. Messrs. Arnold and Messrs. Mayer and Meltzer (London) had also a valuable collection of surgical and medical instruments. Schall (London) had on exhibition various specimens of electrical appliances. Young J. Pentland, the medical publisher and bookseller of Edinburgh, exhibited some new and important publications at extremely moderate prices. In Section 3 there was a collection of anatomical and pathological specimens, with microscopes by Beck of London and other makers. Mr. F. Wetherall Stoney exhibited the head of a mummy taken from a tomb lately opened at Assouan on the Nile. In the section which dealt with hygienic and sanitary

Digitized by Google

appliances, Messrs. Boyd (Belfast) showed the "Doctor's Ulster," of which they are the inventors and makers. Messrs. Fletcher and Philipson (Dublin) exhibited their patent accessible system of drainage, automatic flushing tank, and Hecla water heater. Messrs. Bellington Bros. (Liverpool) had also a good display. The Sanitas Company showed specimens of disinfecting fluid and antiseptic gauze. Non-arsenical wall papers were exhibited by Messrs. Woollams and Co. (London), &c. Besides these we may mention Ross's invalid furniture; the Longford wire mattresses; Kehoe's portable operating table; O'Brien's mineral waters, of excellent quality; Corcoran's splint for excision of the knee joint, devised by Coppinger. While Messrs. Fannin exhibited Neville's traction midwifery forceps; Duke's gynæcological instruments; Hayes' splint; Sir G. Porter's artery compress; Milne's antiseptic dressings; Hewitt's nitrous oxide gas and ether appliances; Mason's beef lozenges; Mr. Ormsby's surgical operation chart; Dr. Richard Hayes' ether freezing microtome, &c.

IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.

DURING the meeting of the British Medical Association in Dublin last week, the summer general meeting of this Association was held in the museum buildings of Trinity College, and was presided over by Professor Gerald Yeo, in the absence of Sir Thomas Crawford. Dr. Stewart (provincial honorary secretary) reported that the Council had requested Sir Thomas Crawford to propose a resolution at the annual meeting, held that same afternoon, of the British Medical Association, bearing on the question of the exclusion from higher appointments in English hospitals of Members and Fellows of the College of Physicians in Ireland, and of Fellows of the Irish College of Surgeons. The efforts of the Association had been so far successful that, although the actual resolution proposed by Sir Thomas had not been adopted, a similar one having the same effect had been carried by an overwhelming majority. The Chairman proposed an alteration in one of the rules, making it necessary for one-fourth of the members of the Council to retire each year, which was adopted. The summer dinner took place subsequently at Morrison's Hotel, when fifty-six members and guests were present. The usual toasts were given, and the reunion was a very agreeable one.

THE INTERNATIONAL MEDICAL CONGRESS.

OUR New York correspondent furnishes the following information for the benefit of intending visitors to the Congress:—

The arrangements for the meeting of the International Medical Congress are progressing to a very satisfactory conclusion, and it may interest your readers to know some of the details, as far as they pertain to the comfort and convenience of foreign members. The Congress meets at Washington on September 5th (Monday) and continues until the close of September 9th (Friday evening). The rates of transportation by the various steamship companies are fixed as follows for members of the Congress: Antwerp to New York and return (Red Star Line), $100; Liverpool to New York and return (Inman Line), $100; Hamburg to New York and return (Hamburg Line), $90; Amsterdam to New York and return (Royal Netherlands Line), $80; Bremen to New York and return (North German Lloyd Line), $187 50c. The same rates are allowed for the families of members. The Cunard Line allows 10 per cent. reduction for members and their families; the White Star Line, from Liverpool, has fixed the same rate. The Anchor Line, Glasgow to New York and return, has fixed its rate for members at £20. The Compagnie Générale Transatlantique (Havre to New York) has fixed the rate at a reduction of 30 per cent., or 700 francs ($140). On arriving at New York members will meet a Committee of Reception, which will immediately provide hotel accommodation at reasonable rates, and afford them every possible facility for their comfort and convenience. The principal hotels for members are the Fifth Avenue, Bartholda, Victoria, Murray Hill, Gilsey, Brunswick, Park, and St. James's. Members of the Reception Committee can be found at any of these hotels. It is the intention of this committee to have full directions to foreign members furnished to all the steamship lines for their information in advance of their arrival. The journey from New York to Washington occupies about six hours. The members on arriving at Washington will find ample accommodation furnished by the Committee of Arrangements, of which Dr. A. Y. P. Garnett is chairman. The hotels are—Rigg's House, Arlington Hotel, Willard's Hotel, Metropolitan, and National. The average rate is $3 per day. When the final arrangements are all completed the programme will be published, and every steamship and each United States consul will be furnished with full particulars, with instructions to give information to all who may inquire.

Dr. A. Y. P. Garnett, chairman of Committee of Management, has issued a general programme of arrangements for the meeting of the Congress, of which the following are the principal details:—First day (Monday, Sept. 5th).—The Congress will assemble at Albaugh's Opera House at 11 A.M., and will be formally opened by the President of the United States, to be followed by a short address of welcome by the Secretary of State; address by the President of the Congress; report of Secretary-General and Chairman of Committee of Arrangements. Adjourn at 1.30 P.M. From 3 to 6 P.M., meeting of the Sections at their respective halls. Evening *conversazione* at U.S. Pension Hall, from 8 to 11 P.M. Second day (Tuesday, 6th).—Meeting at 10 A.M. at Albaugh's Opera House. General addresses by Drs. Flint and Semmola. Sections will meet at 11 A.M., and adjourn at the same hour, with Congress at 1 P.M. In the afternoon the Sections will meet from 3 to 6 P.M. In the evening it is expected that a reception will be given by the President of the United States, and the Corcoran Art Gallery will be thrown open to the members and their families. Third day (Wednesday, 7th).—The Congress will meet at 10 A.M. General addresses until 1 P.M. The Sections will meet, as usual, at 11 A.M., and adjourn at 1 P.M. Afternoon meeting of the Sections from 3 to 6 P.M. Evening reception to the members and their families by the citizens of Washington. Fourth day (Thursday, 8th).—General meeting at 10 A.M. Addresses, if not previously delivered. Meeting of the Sections at 11 A.M.; adjourn at 1 P.M. Afternoon, Sections meet from 3 to 6 P.M. General reception buffet banquet at U.S. Pension Hall, from 8 to 11 P.M. Fifth day (Friday, 9th).—General meeting at 10 A.M. Transaction of business affairs of Congress. Meeting of Sections at 11, and adjourn at 1 P.M. Afternoon, Sections meet from 3 to 6 P.M. Sixth day (Saturday, 10th).—General meeting at 10 A.M. Adjourn at 11, for visit to Mount Vernon. On Sunday or Monday, the day not yet determined upon, an excursion train will leave Washington with the foreign members and their families for Niagara Falls, under the escort of a part of the Committee of Arrangements, selecting the route which will afford visitors an opportunity to see some of the most interesting and thrifty portions of the country, as well as very beautiful scenery. In completing the details of this programme it may, however, be necessary to make some slight modifications.

The Congress being a society established for philosophical and scientific purposes, books, maps, and charts (not more than two copies in any one invoice), philosophical and scientific apparatus, instruments and preparations, casts, paintings, drawings, and etchings, specially imported in good faith for the use of said Congress and not intended for sale, are entitled to free entry under the provisions of the Tariff Act now in force in America.

A TRIP TO INDIA.—The P. and O. Company are bringing before the public in a practical form the fact that a trip to India and back, with a stay of from two to three weeks there, is capable of accomplishment within the compass of a two-months' holiday or even less. The Company's fine new steamer *Victoria* of 6500 tons, the latest and most luxuriously fitted of their large fleet, is to leave London on Oct. 1st for Bombay, touching at Gibraltar, Malta, Egypt, and Aden *en route*. A stay of twenty days at Bombay will give ample time for visits to places of interest in India, and on Nov. 11th the *Victoria* will return, calling at Naples on her homeward journey.

THE LANCET.

LONDON: SATURDAY, AUGUST 13, 1887.

THE statements and petitions submitted to the Privy Council by the various bodies immediately interested in the formation of a new University with local privileges and duties in the metropolis have recently been made public, so that we can now judge of the value of the arguments that have been advanced on both sides of the question. The Royal Colleges in their draft petition and Charter simply ask for powers to grant degrees in Medicine and Surgery, under rules to be drawn up by a Senate of forty-eight physicians and surgeons—viz., the Council of the Royal College of Surgeons for the time being, and twenty-four Fellows of the Royal College of Physicians elected for that special duty. Such a Senate would also supervise all the arrangements for granting such degrees, except that by the Charter no degrees can be conferred on any person who has not already passed the qualifying examinations of the two Colleges either jointly or separately. This movement, which would practically convert the two Colleges into a University with a single Faculty—that of Medicine only,—has received considerable support on the ground that this plan affords the most promising commencement of a real University for London; many thinking that if degrees can be obtained by London medical students on equitable terms, the profession should demand nothing further, and leave the other Faculties to do the best they can for themselves. This position is quite untenable. Every University and every University graduate will, with perhaps the exception of London and its *alumni*, oppose a one-Faculty University. They will urge that it must be complete in Laws and Science as well as Medicine, or its prestige will be *nil* and its degrees worthless; and we fear that the opposition to this scheme on these and other grounds, especially the provincial objections to a residential clause, are underrated by its most conspicuous advocates. If such a scheme were approved by the Privy Council, it would certainly remove a real grievance now suffered by the London medical student, but would do nothing for the higher academic education of the metropolis; indeed, it would tend to delay for a lengthened period any solution of this difficult problem. If medical degrees were granted by the Corporations without any relation to or connexion with Arts and Science, the establishment of a complete local University would probably be postponed indefinitely. The reasons for promoting a Teaching University in London, so as to concentrate and afford due status to the bodies which give genuine University instruction in the metropolis, are well set out in the petition issued by the Association established for that purpose; and the essential standpoints of its position are—(1) the injurious effect upon University education in London of the severance of the work of examination for degrees from that of teaching, (2) the necessity of a regular course of attendance on the best attainable teaching as a preliminary to graduation, and (3) the direct and adequate representation and influence of the teacher in the councils and administration of the University. As the two Colleges which alone are fully equipped with chairs, provided with all the necessary aids and appliances for the most modern teaching, and able to undertake such work for the metropolis and the adjacent district, King's and University Colleges have applied for a Charter which would constitute them a University. They propose to form the Faculties of Arts and Science directly from their own bodies, and to take into such Faculties any other properly established and equipped College that should afterwards apply; whilst to form a Faculty of Medicine they would invite the co-operation of the other London medical schools, which should be represented either directly, or indirectly through the Royal Colleges—the better and more workable plan. If there were no jealousies to be overcome, the above scheme would seem to secure both objects—namely, due facilities for obtaining degrees for London medical students on fair terms, as in provincial and Scotch Universities, and the concentration and improvement of the higher education in the metropolitan district. But that the University of London will oppose the independent growth of its two oldest Colleges is evident by the statement which its special committee has drafted. An alternative plan for giving teachers a consultative voice instead of a mere administrative share in the University has been put forward. It reiterates the old objections to teachers being examiners, forgetting that nearly all its best examiners, past and present, have been or are teachers, and in many cases must examine their own pupils. It is also scarcely fair to ignore the fact that external examiners are now joined as assessors with the internal examiners in every other University, and that by this plan the objects aimed at by the London University are completely secured. The obvious inefficiency of a Senate in which teachers are almost absent for regulating and conducting a properly advised curriculum of study is not referred to. Such a Senate can lay down admirable examination rules and frame standards, but can have no adequate conception of a duly adjusted and proportionate course of teaching. Hence the reason why the University of London has become an Imperial Examining Board, and has neglected its proper local functions. There can be no doubt that there is plenty of room for both institutions—a Teaching University for the metropolitan area with its four millions of population, and an Examining Board for the empire, with its local habitation in the metropolis. The objects and aims of the two bodies are so different that any attempt to blend them into one institution would be fatal to both, and there is no reason why they should not flourish independently and even side by side. The success of the Victoria University is a good presage. If the midland district, with Birmingham for its centre and Mason's College as the chief college, were also to found a university, higher education in England would have every needful facility for its promotion, and the University of London would still have plenty of candidates for its degrees.

THE interest which now attaches to the probability of a connexion between the infective diseases of man and of the lower animals, coupled with the lack of information as to the causes of diphtheria, make such a report as Dr. GEORGE

Digitized by Google

TURNER has presented to the Local Government Board more than usually instructive.[1] It appears that Dr. TURNER was last year employed by the medical department of that Board in making a series of investigations into diphtheria, and he has now submitted a summary setting forth certain facts which came under his observation during his work, and which in his mind indicate a relationship between that disease in animals and the same affection in the human subject. He does not for a moment imply that diphtheria as ordinarily met with may not be due in the main to personal spread in connexion with school attendance and otherwise, neither does he exclude as possible causes such conditions as overcrowding and bad sanitary conditions generally. But, after all these circumstances have been allowed to have their full weight, there still remains a number of cases, and these at times the initial ones in certain outbreaks, which cannot be explained in the ordinary way, and as to which some novel facts have come under his notice, both during his general work as a medical officer of health and in connexion with his recent inspections.

The transmission of diseases of animals to man is well known to take place, and the cases of anthrax and glanders may be cited as examples. Evidence, which some regard as conclusive, has been adduced to show that scarlet fever can be communicated to man directly from the cow through the agency of milk, and this in connexion with a disease in the animal not yet sufficiently defined; and there now appear strong grounds for believing that some such transmission can take place in diphtheria, and this from more than one animal source. In 1882 Dr. TURNER found that pigeons suffered from a disease in which the windpipe was covered with a well-marked and consistent membrane, resembling that found in membranous croup; and inoculation of other pigeons with this membrane led to the communication of the same disease. Then fowls were found to be suffering in a similar manner, and with this occurrence it was noted that on the farms affected diphtheria made its appearance as a sequel to the fatal ailment among the fowls. In 1886 similar cases were observed. Thus at Farnham Dr. TURNER found that the fowls had been affected at the same time as an epidemic of diphtheria was in progress amongst human beings; and the dissection of one of the chickens led to the discovery of a membrane in the trachea. Much the same disease was observed to occur amongst turkeys and fowls at Ash; it had also existed at Long Eaton in Derbyshire; and the disease had made great havoc amongst pheasants in parts of Surrey where diphtheria was also under investigation. Locally, the disease had in some cases been mistaken for such affections as "strangles," but no such possibility influenced the facts detailed by Dr. TURNER. At Tongham the purchase of a chicken from an infected farm was followed by a first attack of diphtheria in the house of the purchaser. Chickens and pigeons inoculated with true diphtheritic membrane from a child's throat were found to suffer from a disease in every point like that which may be termed "fowl diphtheria"; and other evidence is forthcoming to indicate a strong probability of identity between the disease affecting fowls and diphtheria in man.

In another district Dr. TURNER had previously found swine and horses suffering from a similar affection—it being in this case after, and not before, a prevalence of diphtheria in the human subject; but up to 1886 there was nothing to lead to the belief that the disease was communicable from such animals to man. In the case of cats, however, in several parts of the country a disease from which these animals have suffered appeared to have been the source of true diphtheria in a number of households, and fresh facts are being reported now that attention has been drawn to the subject. Cats have also contracted some throat affection from children ill of diphtheria, and Dr. TURNER reminds his readers that the inoculation of cats with diphtheritic material has apparently been successful in the hands of Dr. C. J. RENSHAW. Horses are known to suffer from a disease often styled "strangles," but the affection appears to have some real kinship with human diphtheria, and in certain cases referred to in the report diphtheria at farmhouses and elsewhere has occurred in the families of those having to do with horses thus affected. A large proportion of fatal attacks of diphtheria has also been observed to occur in the families of persons—such as shepherds, grooms, and blacksmiths—who have to do with the lower animals.

The materials put together in this report are most suggestive; they are likely to be of considerable service to medical officers of health and others engaged in the investigation of diphtheria occurrences; and they may form a clue to the origin of those isolated attacks which cannot be attributed either to personal communication or to other ordinarily assigned cause. Dr. TURNER does not profess to have conclusively demonstrated the transmission of diphtheria either from the lower animals to man or from man to the lower animals, and he admits that some of the evidence he brings forward may be open to many objections. But, on the other hand, he believes the facts detailed by him, and which only pretend to include some of the broader clinical and pathological resemblances between the maladies met with, may be of service as indicating a line of research which can be usefully followed out by many of those who devote their time to the study of the etiology of the infective diseases in man.

SIR THOMAS CRAWFORD, who was the hero of a discussion at Dublin, reported last week, on the "relative rank" question, also led a very lively debate on another thorny subject. He moved, in effect, that the members of the British Medical Association were aggrieved by the rules of certain public institutions which select their medical officers from those holding "the higher qualifications of certain Colleges," and that the Association should endeavour to induce the Medical Council to make it clear that the higher registrable qualifications of the Colleges of Physicians and Surgeons are of equal value, or, if they are not, that the Medical Council will take steps to make them so, in order that the candidates holding such qualifications may be equally eligible for such appointments without reference to the nationality of the College from which their qualifications have been obtained. Sir CHARLES CAMERON seconded the motion, and maintained that Irish medical men were in no way inferior to English. Sir THOMAS wisely accepted an

[1] Report of Dr. George Turner's Experience of Diphtheria, especially in its relations to the Lower Animals, partly obtained in the course of Inspections made for the Local Government Board in 1886. Eyre and Spottiswoode, London; A. and C. Black, Edinburgh; Hodges, Figgis, and Co., Dublin.

Digitized by Google

amendment of a simpler character, but to a similar effect, by the Rev. Dr. HAUGHTON—viz., that the Association is of opinion the diplomates of Irish and Scotch Universities and Corporations should possess the same privileges in respect of public appointments as are enjoyed by the diplomates of the United Kingdom. This amendment was carried, in spite of the opposition of several able speakers, by an overwhelming majority.

The subject is not free from difficulties. Theoretically, it is clearly unreasonable that at this time of day a well-educated medical man holding his degree or diploma from Edinburgh, Glasgow, or Dublin should be ineligible for many hospital appointments in England. In many cases the old rule survives only because its narrowness has not been pointed out. But after this admission has been made, it has further to be allowed that there has been a basis of reason in the distinctive privileges of those holding the higher qualifications of England. It is notorious that until very lately the Fellowships of the Medical Corporations of Scotland at least could be practically bought, with little reference to professional attainments. It would obviously have been unfair to regard the Fellowship in such cases as of equal merit with those of the London corporations. Since this discreditable state of matters was brought to light and denounced, chiefly by ourselves, an examination test for the Fellowship has been instituted in the Scotch corporations. The Glasgow Faculty says its Fellowship examination is as stern as the examination for the Fellowship of the College of Surgeons of England. But we have no outside testimony to this effect. Were such testimony forthcoming in regard to the other Bodies and Nationalities, the English Colleges could not ask for the maintenance of the rule for one day, and if they asked, would not be listened to. It is a little curious to see a man of Sir WALTER FOSTER'S liberal sentiments maintain that this is a mere sentimental grievance beneath the notice of the Association. It is really a very serious professional grievance, and if the Association is not to grapple with it, we do not know to what body to look for redress. The Medical Council has no power in the matter, as Dr. HAUGHTON well said. Its responsibilities end with seeing that the examinations for the minimum qualifications guarantee competency in all branches of practice. It is a pity that the Council of Medical Education is not responsible for the higher grades of medical education. We have always urged that it should have jurisdiction over these as well as over the examinations which have to be passed for the ordinary qualifications. But Parliament has decreed otherwise, with too much consent from the medical authorities, most of whom seem only too well satisfied if even their higher examinations are reported mere guarantees of fitness for the ordinary duties of practice. Hospital appointments are presumed to involve exceptional duties, and to call for higher tests. The first thing to be done in this matter is for the Scotch and Irish bodies to show that their higher titles are only given on conditions as severe as those of England. If proof to this effect can be adduced—and it should easily be forthcoming—no English monopolies can be defended for a moment. It will still remain a question—a separate question—whether high professional appointments should not be given only to those with high professional qualifications. But it will no longer be seemly, or even tolerable, to maintain privileges for those holding the diplomas of a certain nationality as against those who have passed examinations of equal severity elsewhere. This question ought not to be lost sight of by the Association.

THE supporter of the doctrine that the particulate ingredients of the atmosphere are the chief cause of the insalubrity of cities will find much to sustain his contention in the brief but suggestive paper contributed by Dr. FRANKLAND to the current number of the *Nineteenth Century*. From the facts presented the proposition might easily be maintained that "a man carries with himself the elements of his own destruction." Many arguments of a seemingly valid sort may be educed from hygienic and antiseptic systems, calculated to prove that a germless atmosphere would be far more profitable to the majority of mankind than the atmosphere with which we have at present to be contented; and this notwithstanding the somewhat contrary position which Dr. FRANKLAND takes at the commencement of his paper, for he thinks it would require but little persuasion to convince most of us that air without organisms would be undesirable indeed. He proceeds to illustrate this view by a reference to the great utility and value of one micro-organism at least—the yeast fungus,—which is so widely and universally distributed, and whose disappearance from the breathing medium would cause us to "forego those numerous, complex, and much appreciated pleasures which are derived from the consumption of alcohol in its various forms."

For our own part, we believe there is already sufficient evidence to warrant a belief that the presence of micro-organisms in the respiratory fluid is very undesirable; whilst we confess at the same time that their exclusion would be practically impossible. Undoubtedly many of the germs in the air we breathe are for the most part harmless in their nature, though it is probable that even the innocuous varieties may require a slight expenditure of energy on the part of the human organism to neutralise the effect of their activities, since it is hardly likely that the act of destruction of a bacterium is unattended with the employment of some kind of force, and we know that the active protoplasm of living bodies is capable of destroying bacteria. Indeed, the theory implied in these considerations may be expanded. We may conceive, for example, that deterioration of health by a general weakening of the whole body might be the cause of many diseases, not so much by the agency of the mere debility as by the circumstance that the deterioration afforded the opportunity for the growth and development of organisms which, under the ordinary circumstances of good health, would have been quickly destroyed by the inherent vitality of sound tissues. The experiments of PASTEUR and TYNDALL, and the observations of MIGUEL and FRANKLAND, bear abundant testimony to the existence of a law which may not be expressible in such definite terms as that the number of microbes in the atmosphere varies inversely as the square of the distance from human habitations, but which nevertheless forcibly reminds one of this physical law. PASTEUR exposed twenty flasks containing putrescible substance in the open country of Arbois, and found that eight became turbid or contaminated with microbes. Of twenty exposed in the

Digitized by Google

lower heights of the Jura mountains, only five became affected, whilst of twenty others exposed at the Montanvert, close to the Mer de Glace, at a height of 6000 feet, only one flask developed microbes. MIGUEL, by observations made at Montsouris in different seasons of the year, has shown how the distribution of microbes is dependent on the surroundings. FRANKLAND, employing a more recent and more acourate method, has shown very clearly that the maximum number of micro-organisms is to be found in the hottest months of the year. Thus, in a volume of air equal to about two gallons (ten litres) collected on the top of the Science and Art Department buildings at South Kensington, at a height therefore of some seventy feet from the ground, and so removed from any local disturbance of the air, he found that in August the number of micro-organisms exceeded 100, whilst in January there were but 5; there was a gradual rise in numbers from May to August, after which the fall in numbers was much more sudden. In the country the number of atmospheric micro-organisms was very appreciably smaller; and the more remote the place of observation is from houses, and from the frequented thoroughfares of traffic, the dust of which is always rich in refuse organic matter, the freer does the air become from suspended microbes. In reading Dr. FRANKLAND'S paper, one cannot but be struck with the remarkable concomitant variation between the number of micro-organisms and the unwholesomeness or wholesomeness of the places investigated. Every medical man knows the value of mountain air and of a sea voyage, and it is only in these places that the atmosphere can be said to be free from micro-organisms. The interiors of railway carriages are, as we all know, apt to become foul, but Dr. FRANKLAND'S estimation that more than 3000 organisms were found to be falling on the square foot in one minute whilst the train was passing half way between Cambridge and London, one window of the compartment being shut and the other only open four inches at the top, gives a mathematical expression to the fact, which, if any were wanted, is sufficient explanation of the fatigue of a journey, without invoking the aid of the theory of nerve vibration to account for the prostration which many suffer after a prolonged ride in the train. In point of numbers, however, the atmosphere of a barn where flail threshing was in operation puts the railway compartment in the shade, for there were no less than 8000 organisms falling on the square foot in one minute. The injurious effect of theatres and crowded places of amusement would find a sufficient explanation in the yield of micro-organisms, without taking any account of the diminution of oxygen or the increase of carbonic acid. At a conversazione at Burlington House the number of organisms reached 432 per ten litres of air.

THE discussion at the meeting of the British Medical Association on the subject of the report of the Parliamentary Bills Committee, to which we called attention last week, raised some very important questions, to which we think it necessary in the interests of the profession to refer. The first of these is whether the alteration in the wording of the Royal Warrant has in any way affected the rights, the status, the prestige of the army medical officers. The Parliamentary Bills Committee assert that it has deprived them of all rank; the Secretary of State for War states that it has not in any way altered their position—that they have the same rank under it, and the same privileges in all respects as they had under the previous Warrant. Which of these two statements are we to believe—that of the irresponsible committee above referred to, or that of the War Minister, who is liable to be called to account if he does not redeem his pledge? Another question raised is a very important one—that of the right of army medical officers to make a "collective representation" of their opinions when they differ from those of the responsible authorities; and credit was claimed for the Parliamentary Committee in having afforded the medical officers such an opportunity. Sir THOMAS CRAWFORD very distinctly stated that "every medical officer in the army having a grievance was at perfect liberty to address his chief." The question at issue, therefore, is whether a collective statement on their part—a round robin, in fact—is permissible. But if this were granted, how could it be confined to the medical department? Why not be extended to all the army departments? And if to the departments, why not to the officers of the staff and of the various corps? If granted to the army, why not to all the branches of the Civil Service? Simply because it would render the conduct of the public service an impossibility. It has been asserted—but we are not aware of any instance of it being adduced—that in consequence of the alteration in the wording of the Warrant military officers will refuse to acknowledge the army rank of medical officers, and deprive them of the privileges attaching to such rank. We do not believe any military officer will be so unwise; but if it did happen, there is an obvious remedy. A report of the circumstances to the Director-General would soon put matters right, and we should not envy the military officer the position in which he would find himself placed in consequence of such an act. To suppose that such a report would injure the officer who made it, or interfere with his prospects, would imply an utter ignorance of the manner in which the service is conducted. It is rather amusing to see the change which has come over the question at first raised on the subject of relative rank. In the document issued from the offices of the British Medical Association there is no reference to any injustice done by the recent Warrant. The whole matter is one of title. What would you like to be called? Will you have a purely military designation, or a purely medical, or a hybrid medico-military, or will you be content to remain as you are? This bears out the opinion we have repeatedly expressed, that at the bottom of the agitation is a desire on the part of some men to sail under false colours and assume a pseudo-military title instead of their correct and honourable professional designation. Whatever may be the result of this *plébiscite*, we do not believe that the teachers in the medical schools, or the profession generally, will be induced to support the attempt to sink the medical under the military appellation, nor do we think the War Minister is at all likely to adopt any suggestion of the kind.

AN Exhibition of Hygienic Appliances and of Articles of Diet, as well as of other matters connected with public health, will be opened at Boulogne-sur-Mer on Sept. 21st next. M. Pasteur has accepted the presidency of the Exhibition Committee.

Annotations.

"Ne quid nimis."

MEDICAL ATTENDANCE IN WORKHOUSES.

THE two letters on this subject which have appeared in our columns are entitled to much consideration. But they do not militate against our main contention that where hundreds of people are congregated in great infirmaries they should have the benefit of a second medical opinion. One of our correspondents says that they have this already in the shape of a principal and an assistant medical officer. It is not generally held that a principal having an assistant, however qualified, is able to dispense with the advantages of the occasional suggestions of a consultant, or one in whom he can recognise an authority or experience superior to his own. This same writer, Mr. Henry Dixon, points out that the appointment of consulting physicians and surgeons is already under consideration in the case of some workhouse infirmaries, and Mr. Mickle, in his excellent letter, admits that the question is one open for discussion. It is not one to be hastily disposed of. The discussion involves no disrespect to the existing officers, and no want of sympathy with overburdened ratepayers. This country is rich enough to do all that humanity requires to its in-door poor, and there are consultants enough to be had without greatly oppressing the taxpayers. But the workhouse infirmaries are practically hospitals on a large scale, and though the bulk of the diseases are chronic and progressive, and but little under the control of art, there are many exceptions: and even the victims of the most hopeless diseases and degenerations have a claim of their own. We feel confident that the best medical officers will not feel either their responsibility or the interest in their cases lessened by co-operation with a consultant. We agree that such an appointment should be made by the guardians, and that it is not desirable or permissible that outsiders should be introduced at the mere caprice of friends. Mr. Dixon seems to think that the poor inside would be better off than the poor outside. He should remember that the hospitals of London, with all their highly educated and experienced staffs, are at the service of the poorest man who may need surgical or medical help.

PROFESSOR SIR GEORGE MACLEOD'S ADVICE TO YOUNG GRADUATES.

THE address of Sir George Macleod to the new medical graduates of Glasgow on the 28th of July was an admirable one. There was nothing pretentious in it in respect of novelty or philosophy, but as advice from a senior and a professor to men who had finished the academic part of their study and were about to encounter the stern duties of medical life, it should have effects in many a distant year. How shall we summarise Sir George's main points? He thinks medical men of the younger generation have much to rejoice at in being educated under what he terms the New Dispensation. By the discoveries of Pasteur, Medicine has been revolutionised and advanced more than in the preceding century. Such work he considers ample answer to Sir William Hamilton's scornful question, "Has the practice of Medicine made a single step since Hippocrates?" There is a wonderfully true paragraph descriptive of the triviality of the circumstances that may determine the career of young men just going out into the world, including the advice not to be too fastidious in the choice of a first appointment so that it secures experience. He enforces this by reference to the disproportion between the few vacancies by death arising in the profession, and the large additions to it by the new registrations. The annual average of the latter for eleven years is 1152; of the former, 588. The waiting-time for practice is to be used in reading much, but in working more, as Carlyle advised. The reading must be general as well as medical, and Baconian carefulness in the observation and record of facts must be practised, if Sir William Hamilton's words are not to be realised: "I think it more than possible that in fifty or a hundred years the business of a physician will not be regarded even in England as either a learned or a liberal profession." Perhaps Sir George scarcely does full justice to the profession in his allusion to the slipshod language and inconsequent reasoning of medical discussions. There is of course much truth in this, but there was never more severity of reasoning in medical discussions than there is now. His caution to men who have taken honours in the University is well put—not to make too much of that fact. His advice against a premature or ill-assorted marriage is much needed. It is not fair to the woman, and it sorely cripples the man. Not less opportune is his warning against mere fashion and quackery in the prescription of new drugs. He commends the high teaching of Hippocrates and the oath administered to his pupils: "With purity and holiness I will pass my life, and practise my art." Before his peroration Sir George Macleod sounds two apt notes of counsel. First: "In your dealings with professional brethren, avoid quarrels and petty jealousies," though he denies that such things are more common in our profession than in others. The second has reference to the "grave responsibility" of prescribing stimulants and narcotics: "My decided impression is that intemperance in such things is largely on the increase. . . . Avoid these agents, then, if possible, or, at least, limit and control their use, and do not risk incurring the anathema of having contributed to ruin a fellow-creature."

"MARGARINE."

IT has now been decided that the word margarine will be adopted as a generic name for all butter substitutes. We regret the decision for several reasons. In the first place, the word margarine conveys a definite idea to the mind of every chemist, and that idea is quite different from that intended by the Act of Parliament. The substance properly called margarine is the glyceride of margaric acid—the tri-margarate of glyceryl. This substance is not present in any butter substitute, and the use of the name is therefore misleading. It is as absurd as it would be to describe all bitter principles as quinine. Then we believe that the word margarine is calculated to raise an unjust prejudice against an article of food which, when properly made, is agreeable in flavour, of considerable dietetic value, and very cheap. Of course there are various qualities of butter substitutes, as there are various qualities of butter. Some are highly objectionable, and their manufacture and sale should be sternly prohibited. Any such manufacture in England ought in future to be impossible, as the new Act compels all manufactories to be registered. There will be greater difficulty with foreign brands, but it can doubtless be overcome by careful analysis. But as for good "margarine," its use ought to be promoted rather than hindered, and the enforcement of a name so unfamiliar to the public and so absurd to the scientific man as margarine is likely to be a hindrance. We fear the whole outcry arises less from a desire to protect the public against adulteration than from the hope that in this way protection may be gained for the farmer. If the sale of cheap butter substitutes could be greatly checked or annihilated, the price of genuine butter would undoubtedly rise, which would be good for the farmer though detrimental to the consumer. It is no part of our duty to argue the case of free trade or protection; but we think all will agree

Digitized by Google

that if protection be desirable, it ought to be adopted openly and boldly, and not smuggled in by a side wind. Let us not be understood as offering the slightest excuse for adulteration. Our opinion in that matter is not likely to change, and we hold that the sale alone or in mixture of a butter substitute under the name of butter is a commercial fraud that ought to be severely punished. But, provided the article or the mixture be correctly described, we see no sense in checking by a name which to the great majority of mankind will appear opprobrious—the sale of a good and cheap substitute for butter. Surely it would be possible to find a name less open to objection from a scientific point of view and more fully expressive of its nature and use. The word "butterine" is too suggestive of a family relationship with milk-butter, which the article does not possess.

THE STATE OF THE THAMES.

THE Metropolitan Board of Works seem at last to admit that the tidal portion of the Thames is in a horrible and dangerous state. At any rate the Home Secretary admitted as much in reply to a question asked by Colonel Makins the other day. It is almost incredible that they should have ignored such a mass of evidence, including the evidence of their own senses, so long. They have resisted all advice tendered to them, and all pressure put upon them, and when at last forced from their position have retreated as slowly as possible, and have adopted the least satisfactory of remedies. Their disinfection of the sewage has proved, as it was bound to prove, a costly sham, and their new remedial works are all to be erected in the wrong places, and will certainly lead to no cure for the evil. The amount of the ratepayers' money which has been, and is still being, thrown away by the Board in respect to this great question will perhaps never be known, but it is certainly enormous. An army of labourers and skilled workmen is now at work, and will remain at work for a long time to come. Its labour and the cost which it entails with the steamers which are to carry the sewage sludge to the sea will all be thrown away, for no one believes that London will long remain satisfied with so paltry a substitute for a real remedy. With regard to the condition of the Thames as a source of supply of potable water for the metropolis, the question being one of such magnitude and interest at the present time, we have deemed it wise to send Commissioners again to investigate the state of the water in the vicinity of the intakes of the London Water Companies which derive their supply from the river Thames. The conclusions of our Commissioners, which will be found in another column, we commend to the serious attention of sanitarians.

BORACIC ACID AS A MILK PRESERVATIVE.

THE Vestry of Kensington recently referred to their medical officer of health (Dr. Dudfield) and public analyst (Mr. Cassal) the question whether the addition of a small quantity of borax, or, more properly, borax with free boracic acid, to milk was injurious to health, and should therefore be treated as an offence against the Food and Drugs Act. The question is an important one, for the more strongly we reprobate adulteration and punish its perpetration, the more necessary it becomes to be sure that the offence has been committed. The report of the scientific officers is now before us, and the results may be stated in a few words. There is no doubt that the above-named preservative is frequently used by farmers in the country and by milk vendors in towns, perhaps sometimes by both. The quantity used is said to be seven grains per pint for milk and four grains for cream. As there is a manifest possibility that it may be used twice over, not to speak of the risk of its being used in excessive quantity through carelessness or ignorance, the reporters are right in assuming that each quart of milk may contain twenty-eight grains of the preservative. This would mean an increase in the ash of 0·16 per cent., and even the half of this would be very perceptible in the analysis, for the ash of genuine milk seldom exceeds 0·7 per cent. It is manifest that this is no fraudulent addition in the common meaning of the term, for it does not add appreciably to the bulk of the milk, and cannot be used, as alum is in flour, to disguise a deficiency in quality. The antiseptic power of boracic acid is well known, and if it were proved to be innocuous its use would be commendable, as tending to prevent the waste of much valuable food material. But unfortunately its harmless character is more than doubtful. There is, indeed, but little direct evidence available, but that little is decidedly against the drug. The most important is the memoir of Professor J. Förster,[1] for a translation of which, published in another column, we are indebted to the courtesy of Mr. Charles Hancock of the Kensington Vestry. It appears from this research that even small quantities of boracic acid are capable of exerting a distinctly injurious action on the human organism, hindering the assimilation of albuminoids, even in articles as digestible as eggs and milk. Such an action would be most serious in regard to infants and objectionable for all, and we must therefore regard the use of the preservation in question as a dangerous adulteration, which ought to be strictly prohibited. The caution is well worthy the attention of public analysts.

"WHAT IS PAIN?"

"WHAT is pleasure?" "What is life?" "What is death?" It is astonishing to recall the number of unanswered, perhaps unanswerable, questions which have for ages excited the curiosity and exercised the ingenuity of intelligent thinkers. As knowledge extends its area and becomes more exhaustive and precise, hope is stimulated, and every now and again someone thinks and endeavours to persuade those around him that he has found, or is about to discover, the solution of one or more of these enigmatical propositions; but, as yet, all such beliefs and anticipations have ended in disappointment. The true test of success will be the possibility of shaping a satisfactory definition of the thing sought for. At present this is impossible in regard to each and all of the abstruse subject matters in question. Thus no one can define life or death, and pleasure and pain are equally incapable of definition, or even of accurate description. We think we know what it is to live and feel pleasure or pain, but when we attempt to express our thoughts by words we discover that the feat is impracticable. The answer to the question, "What is pain?" must therefore be, "No one knows." This is how far we have proceeded in the quest for a definitive answer. Pain is a sensation which more or less rapidly and acutely assails the faculty of endurance. In its commonest forms it is suffering produced by nerve excitation, the elements of the nervous apparatus being either directly or by a transmitted irritation mechanically disturbed: for example, *compressed* as in squeezing or bursting pain; or *stretched*, as when the pain is aching or tearing; *bruised* or *lacerated*, as when the pain is due to a cut or wound of some sort. It is not of course always the fact that these mechanical injuries to nervous tissue take place at the point to which pain is referred, because, being a sensation, pain is *felt* at some seat of sensation that is in connexion with the sensory apparatus affected, although it may be remote from the point where the impression is produced. In short, pain may be a message of suffering sent from some injured part through a chain of nerve-elements as a message of word-symbols is trans-

[1] Dingler's Polytechnisches Journal, 1884, p. 170.

Digitized by Google

mitted by a telegraphic wire. The purpose of pain is doubtless protective. The sensation is the warning sign of injury, and cries for relief, not simply for the avoidance of suffering, but for the remedy of a state or condition which threatens the integrity of the tissue or organ in distress. It is in this light that pain should be regarded. It may be heroic to bear necessary pain, but to turn a deaf ear to the warning cry of pain is to commit an act of folly.

VACATION COLONIES ON THE CONTINENT.

SANITARIANS will hail with satisfaction the announcement that the system of sending town-bred children into the country for a few weeks during the summer holidays, which has already to some extent been carried out by many philanthropic individuals and associations, both in this country and on the Continent, is to be still further promoted by an International Congress at Zurich next year. A good deal of interesting information with regard to the progress of this movement in several continental countries is supplied in a pamphlet by M. Bion, a pastor in Zurich, which is published by the *Musée Pédagogique*, also in some articles which have appeared in the *Revue Pédagogique*, and in a paper by Dr. Delvaille of Bayonne in a French medical journal. In 1876 M. Bion took 68 Zurich children to the mountains of the Canton Appenzell, where they were distributed in sections of 20 or 30 amongst different localities under the supervision of masters and mistresses. This was repeated each year, the number of children and teachers partaking in the annual excursion gradually increasing. In France M. Cottinet inaugurated the movement in 1883 by sending 9 boys and 9 girls from Paris into country boarding schools where they were well looked after, but made to run about and play all day, with the exception of one hour devoted to instruction, and the necessary time for making their beds and washing and cleaning their clothes and themselves. In succeeding years much larger numbers of little Parisians were taken into the country. The success from a hygienic, to say nothing of the moral, point of view was all that could be desired. The average increase of weight amongst the girls was 2391 grammes during the month's holiday, whereas the normal increase in that time is put by Quételet at only 291 grammes. The mean growth, too, was 20 millimetres as against the normal monthly growth, as estimated by Pagliani, of 2 millimetres; that is to say, during the month in the country they increased in weight and in height something like ten times as much as such children under ordinary circumstances would do. In Italy vacation colonies have been taken from Milan, Venice, and Palermo into the country. In Germany four or five thousand children were sent in 1885 to inland or seaside watering-places. A congress was held in Berlin in 1881, under the presidency of Dr. Falk, which was attended by representatives from Austria and Switzerland, and a discussion held on the question as to whether taking colonies under the care of teachers and locating them in the temporarily vacant country schools is, on the whole, to be preferred to the plan of boarding the children out separately amongst peasant families in the country. Of course, each plan has its own advantages. From the pecuniary point of view, the Swiss pastor's experience is that there is little to choose between the two systems, as neither of them cost anything at all. In Denmark 7000 children were sent in one year to families who received them gratuitously. The children that cannot be taken a long distance into the country have in some places, as in Zurich, been assembled daily in buildings outside the town, well fed, and taken into the fields and the woods to play. The basis of selection is sometimes made the weight, or rather want of weight, of the children. Thus, according to Dr. Warrentrapp, the Frankfort children who were taken into the country one year weighed from two to twenty pounds less than they ought to weigh. These all gained from two to eight pounds during their three or four weeks' absence, and, what is more, continued to gain considerably for some months after their return.

THE EFFECTS OF HEAT AND DROUGHT.

THE excessive heat and drought are having a prejudicial effect upon the mortality returns, and this especially in the large towns and cities. Up to July 30th there had, during the six preceding weeks, been an increase in the general rate of mortality in London from 15·9 to 24·8 per 1000, and although there was a decline last week to 21·7, yet the death-rate this quarter has so far averaged 1·1 in excess of the mean rate during the corresponding period for the ten preceding years. Diarrhœa has been a prime cause in this increase. Thus, during the eight weeks ending July 30th, the fatal attacks attributed to diarrhœa and dysentery rose from 9 to 517. Last week there was a decline to 432, this being 144 in excess of the mean average for the week. Of this latter number 350 were infants under one year of age. During the same period 9 deaths were attributed to cholera or choleraic diarrhœa. This is 4 below the corrected average, and it is probable that the diminution may be due to the adoption of a more correct nomenclature as regards a disease which should certainly not be styled cholera. The long-continued drought is likely to be the cause of much inconvenience and serious mischief. In many places the water supply is already at its lowest ebb, and even where anxiety on the score of the quantity available is not immediately pressing, sanitary authorities and water companies are husbanding their supplies; so that at a time of the year when it is of all others most desirable to be lavish with water for the flushing of drains and sewers, the utmost economy has to be observed.

AN UNHEALTHY HOUSE.

ANOTHER decision has been given in favour of the tenant of an unhealthy house, and in this case the house was an unfurnished one, being in this respect different from the majority of those in which recent decisions have been adverse to landlords letting unhealthy houses. The case was tried before Judge Stonor, in the Brompton County Court. The plaintiff alleged that in taking the house in question he was assured that it was, as regards drainage and otherwise, in perfect order; and it is further alleged that, on the defendant's suggestion, the plaintiff obtained a written report from the sanitary inspector of the district to the effect that it was in a fair condition,—one or two alterations being, however, suggested. Evidence of sewer contamination soon became clear after occupation, and, skilled advice being sought, it was found that there was beneath the house an old barrel drain containing several inches of filth deposit, an absence of any disconnecting trap between the sewer and the back drain, defective bell-traps, old D-traps to the closets, and other conditions now so well known to be associated with conditions of drain poisoning and ill-health. The defendant, however, refused to remedy the evils, and the result was that the plaintiff got the work done and then applied to the Court for the cost of the work, his expenses, and the rent of apartments he had lived in during the execution of the works—some £30 in all. The judge advised the parties to come to terms, but as they failed to do this a verdict for the plaintiff for £25 and costs was given. The case is one of importance, and intending householders will do well to fortify themselves in a similar way by getting an

Digitized by Google

assurance from the landlord as to the sanitary state of the house. Should this assurance prove untrustworthy, they will be able to act on the precedent which this case affords. Incidentally, we may observe that, unless inspectors of nuisances hold the certificate of a competent body as to their fitness for their duties, it is most unwise to trust to their opinion on such points as are involved in this case.

INJECTIONS OF CARBOLIC ACID AND HYPEROSMIC ACID.

No one probably lays claim to a complete knowledge of the pathological changes which give rise to the condition or conditions known as muscular rheumatism, but it may fairly be supposed that they include a hyperæmic state of the perimysium, together with some plastic infiltration and migration of white blood-corpuscles. Now it was shown by Binz that carbolic acid, salicylic acid, and several other substances possess the property of paralysing and killing leucocytes, and of preventing their migration. This led Dr. Edgar Kurz of Florence some few years ago to employ intramuscular injections of a 2 per cent. solution of carbolic acid in a few cases of muscular rheumatism. The results were astonishingly satisfactory, and were published in *Memorabilien*, 1882, from which source a notice appeared in many other journals; not, however, always very correct as to the doses employed, grammes having been mistaken for grains—a misconception which, however important, is often very difficult to avoid, as those who read many foreign medical journals know only too well, simply because abroad "gr." sometimes stands for grains and sometimes for grammes, and as a gramme is more than fifteen grains the consequences of a misunderstanding on this point may frequently prove serious. Dr. Kurz introduced from eight to forty syringefuls into the muscular tissue at a sitting, each syringeful consisting of a gramme of the solution. In no case was the urine discoloured, or any other sign of toxic action observed; the injections were practically painless, and their anæsthetic effect became apparent in half an hour. Since these observations were published Dr. Kurz has continued to employ this method with excellent results. He has also found it very efficacious in the inflammatory affections of the sheaths of tendons due to injuries, and generally in sprains where the ligaments, tendons, or muscles were affected. Some similar and even more universally successful results have this year been published by Professor Benedikt of Vienna from the use of the same solution in affections of the ligaments and tendons but more especially in acute rheumatism, where it appeared to act similarly to salicylate of soda, quickly reducing the pain, the swelling, and the pyrexia. The best results were, however, obtained by combining the two methods, particularly at the commencement of the disease, giving large doses of salicylate by the mouth and at the same time from one to three injections of carbolic acid daily. A somewhat similar form of treatment has been very successfully employed by Dr. Stekoulis of Constantinople in sciatica, an affection due to causes of very various nature, but frequently allied pretty closely with chronic rheumatic affections. The injection he used was a solution of hyperosmic acid, a substance which is in constant request by pathologists for hardening tissues for microscopical purposes. All the ten cases in which this remedy was employed were of considerable standing and very obstinate, Jacoby having recommended its use under such circumstances. A 1 per cent. solution was used, which, on account of the action of light upon it, was preserved in dark glass bottles. One gramme was injected deeply into the gluteal region close to the nerve, and this was followed by other injections extending along the course of the nerve to the number of something like a dozen. The pain caused by the injections was somewhat severe and burning, but it only lasted one or at most two minutes. At first the injections were repeated daily, afterwards every three or four days. Care was required never to insert the needle into the same point as before. Out of ten cases, eight were completely and one partially cured, one only remaining unbenefited. No unpleasant effects beyond a slight tenderness over the points where the needle had entered, and which did not last more than a day or two, were observed.

EARLSWOOD ASYLUM.

PROBABLY most persons are apt to associate with the term "idiot" an entire absence of the mental faculties, and a consequent total incapacity for acquiring knowledge or for doing work of the most elementary kind. The report which is annually issued by the managers of the Asylum at Earlswood, Surrey, goes far to prove that this is, in a majority of cases, an erroneous supposition. The institution during the year ending March 31st, 1887, contained 569 inmates. Of these between 300 and 400 receive some sort of education, and while in the case of some this implies but a trifling measure of success in instruction, there are not a few others whose naturally feeble intelligence has been materially strengthened in the school of the asylum. The subjects taught include speaking (in the case of deaf-mutes), reading, writing, arithmetic, religious instruction, singing, and in two cases mentioned in the last report piano-playing by the ear. The wholesome effect of such light instruction, judiciously communicated, cannot be disputed. Certain trades are also taught, and it is a fact at once creditable to the teachers and indicative of the latent capacity of the idiot and imbecile pupile, that a considerable part of the tailoring and shoemaking of the establishment is done by the inmates. Other trades, such as printing, brush, mat, and basket making, are also taught, with an encouraging degree of success. Recreations, in-door and out-door, very properly occupy a prominent place in the asylum *régime*. The health of the institution during the past year has, on the whole, been good. Several cases of diphtheria have, however, occurred, and the sanitary arrangements are undergoing a thorough revision, with the intention of bringing them up to the present standard of efficiency. The passing af the Idiots Act of 1886, which allows of the admission of weak-minded persons on the strength of a single and simply-worded medical certificate, will, it is believed, encourage many to avail themselves of the advantages of the establishment who have hitherto been deterred by the formal preliminaries required until very recently under the Lunacy Acts. The expenditure of so large a concern as the home at Earlswood is necessarily great at any time, and particularly at present, while sanitary and other improvements are being carried out on an extensive scale. We therefore hope that the liberal support which has brought the asylum to that state of public usefulness in which we find it now will forbid that its work should suffer from the present general diminution of income.

THE REGISTRATION OF "LOCUMS."

IN these summer months, when medical men are so dependent on the assistance of the *locum tenens*, it is often important to be able to ascertain the fact of their registration. This is easy enough if their registration has not been very recent. But where it has taken place in the current year it can only be verified by information from the registrar, and it can easily be imagined that there are difficulties in the way of supplying such information at anyone's request. Yet in the absence of it, it is possible for unscrupulous persons to pretend to be registered, and to palm

Digitized by Google

themselves off as such on honourable practitioners, to the injury of their practice and of their patients. This is not a mere theoretical case. And we advise medical practitioners to be particular in asking all reasonable evidence of statements made by persons who are strangers to them. We often receive complaints that representations made are not confirmed by actual experience. It is only fair to the general body of gentlemen who lay themselves out for *locum tenens* work—many of whom are highly capable men—to use precautions against those who bring discredit on a most useful class. Of course registration is only a legal form of qualification, and is not more important than evidence as to personal qualification, for procuring which each practitioner must rely on himself.

LONDON FIRES.

THE great fire which on Saturday evening last destroyed a large portion of Mr. Whiteley's premises at Westbourne-grove has once more directed public attention to the undeniable insufficiency of the Metropolitan Fire Brigade for the important duty which is cast upon it. It is understood that the responsible authorities feel their deficiency most keenly in the matter of horses; but from the figures that have been made public it would seem that the force is not less under-manned than under-horsed, and that a substantial addition ought to be made forthwith to Captain Shaw's resources both in men and material. The total force includes 589 men. It could hardly be too much to assume that a score, or say nineteen, of these would at any given moment be incapacitated by sickness and the like causes, so that the whole force available could not be reckoned at more than 570. Then, again, a deduction of probably one-half must be made from this number for men off duty, thus leaving not more than 285 ready to answer a summons. The men are distributed through fifty-five stations, and if these are not to be wholly deserted a sufficient force must be left behind to average at least two men to each station. This modest provision would demand 110 men, leaving 175 at the disposal of the superintendent on duty at the fire. The number of men actually mustered at Westbourne-grove is said to have been 173; so that it would seem not only that the entire strength of the force was brought up for the emergency, but also that it was, considering the total strength of the brigade, a very strong and efficient muster. But, although the men respond well to a summons and do their work in admirable style, it is painfully obvious that their number is much too small. A second large fire would on Saturday night have greatly overstrained their powers; and a third, had such a misfortune occurred, would have utterly nonplussed Captain Shaw. Such a contingency as that ought not to be beyond the scope of our precautions.

RABIES IN DOGS.

THE report from the Select Committee of the House of Lords on Rabies in Dogs was issued on the 10th inst. The committee believe that while it cannot be absolutely demonstrated that rabies does not arise spontaneously, yet it is practically proved that subcutaneous inoculation with its virus is the only ascertained means of imparting the disease. The following are the recommendations of the committee:—(1) That when rabies is prevalent the muzzle should be enforced; (2) that the power of the police constable should be extended to authorise the slaughter of stray dogs; (3) that the symptoms of rabies should be endorsed on dog licences; (4) that local authorities should have power to order that dogs should wear badges which may identify their owners; (5) that in populous places local authorities should place restrictions upon dogs generally, and especially deal stringently with apparently ownerless dogs in their districts; (6) that in the event of its being conclusively proved that M. Pasteur's system provides a preventive remedy, facilities should be afforded for its application in England. In our next issue we purpose dealing at length with the report.

DUTCH FACTORY LEGISLATION.

THE Dutch Government, while prosecuting agitators, has thought fit to mitigate the cause of agitation by bringing forward laws for the protection of workpeople. Despatches from the Hague announce that the Committee of the Second Chamber advise the restriction of the work of boys and girls under sixteen years of age, and urge that young women under eighteen should be absolutely forbidden to work at night or on Sundays. The work-day must be divided by two hours' rest for meals, and the committee also advises that women should not be allowed to work till a full month after their confinement. Further, there are recommendations dealing with the inspection of factories and workshops by qualified officials. Laws are proposed to protect the health and personal security of workmen, and measures for creating a reserve fund for old age, deaths, accidents, and illness. How far all these beneficent suggestions will meet with the approval of the Legislature still remains to be seen. The agitation prevailing in the country points to the necessity of some such measures, and doubtless the statesmen of Holland will have the wisdom to yield rather than provoke a dangerous storm. Already, twelve years ago an important measure was enacted of this description. According to the law of September 19th, 1874, the employment of children under the age of twelve is forbidden. Exception, however, is made in cases of domestic service and farm labour. The penalty for breaking the above law is a fine of £2 10*s.* and from one to three months' imprisonment, together or separately. The new proposals actually before the Dutch Parliament go much further than the law of 1874, and undoubtedly the necessity of such legislation is becoming more and more apparent. The vast size of the factories, the presence of complicated, sometimes dangerous machinery, and the difficulties under such circumstances of securing efficient ventilation and drainage, render it more and more urgent to arm the authorities with the right of interference. It is also desirable that at the same time a competent staff of inspectors should be organised who possess scientific and practical knowledge to detect defects, and whose position would place them above the danger of corruption. The working classes themselves must also be able to assist in the detection of all defects that tend to deteriorate public health. They, at least, have the practical experience of the working success or otherwise of any measure introduced; and a little practice is often worth volumes of theory. In any case, and whatever may be the result of the present effort, the Commission of the Dutch Senate are to be congratulated on the useful initiative they have taken.

CHOLERA IN ITALY.

SINCE cholera first appeared in Calabria early in July, there has been a slow but steady extension of the disease. Rocella was at first the principal seat of the outbreak, but it soon appeared that the cholera which in an early part of the year had existed on the eastern coast of Sicily had broken out again, Catania having for some time past been implicated. Gradually the epidemic has extended over most parts of Sicily, the provinces of Calabria, Caltanicetta, Syracuse, Messina, Gergenti, and Palermo being affected. On the mainland a number of additional towns on the Calabrian coast, such as Palmi, Reggio, and Melita, have also been attacked. Then came news as to the extension of the

Digitized by Google

disease to Malta, and to Resina in the bay of Naples. Since Malta was first attacked there has been a daily record of fresh cases, the largest number of attacks having taken place on the 9th inst., when as many as fourteen were returned. Hitherto the troops have remained free from the disease, which is limited to the poorest classes of the population. The last report of cases in Sicily was on the 7th, where fresh cases are stated to have occurred at Messina and Palermo.

THE QUALIFICATIONS NECESSARY IN RETAIL DRUG BUSINESS.

AN important case has been lately before the Justiciary Appeal Court, in the form of an appeal from the Sheriff Court, Edinburgh, against the judgment of Sheriff Rutherfurd in a prosecution against the Leith Depôt Company by Richard Brembridge, London, registrar under the Pharmacy Acts, 1852 and 1863. The essence of the case was that the firm consisted of seven persons carrying on business as wholesale and retail druggists and tea merchants, and advertising themselves as such, while none of them was registered as a chemist and druggist. On their side it was argued that, provided the actual seller and dispenser of the drugs was qualified as a chemist, the law was satisfied, and that the House of Lords had given a decision in this sense. The judges expressed their agreement with the judgment of the House of Lords. Lord Justice Clerk said the Act did not apply to partnerships, and he should very much doubt whether a member of the Corporation could be held responsible, even if the person who carried on the business was not qualified. But he reserved his opinion on that point. Lord Young was of the same opinion, and rather feelingly argued that such companies were in the interest of the public, as supplying drugs at more practical prices than were the rule of the trade.

PROFESSOR SIMON SCHWENDENER.

THIS able worker in the field of vegetable physiology completes a long series of academic triumphs at Zürich, at Munich, at Basel, at Tübingen, and at Berlin by his appointment to the post of Rector in the last named-school, where since 1878 he has filled with much distinction the chair of Physiological Botany. He had already laid the cause of science in Berlin under deep obligations as Director of the Botanic Institute and of the University Botanic Garden. Switzerland, of which he is a native, is justly proud of the high honour conferred on her son, and contrasts the cosmopolitan spirit of German science with the exclusiveness now showing itself in Russian academic circles.

FOREIGN UNIVERSITY INTELLIGENCE.

Cordova (Argentine Republic).—Dr. Johannes Frenzel, of Berlin, who is well known for his researches made at Naples under Professor Dohrn, has been appointed Professor of Zoology, with charge of the Zoological Museum. An eminent German, Dr. Burmeister, who was formerly a professor in Halle, is at the head of the University of Cordova.

Ghent.—Dr. la Housse of Antwerp has been appointed Professor of Human Physiology in succession to M. Mac Leod, who has been appointed to the Botanical chair vacated by the death of the late Professor Kickx.

Jena.—Dr. August Gärtner has been appointed Ordinary Professor of Hygiene and Medical Jurisprudence.

Montpelier.—M. Hamelin, *agrégé*, has been appointed to the Professorship of Therapeutics and Materia Medica. M. Cavalier, Professor of Mental Diseases, has been granted leave of absence for a year.

PROFESSOR VIRCHOW, immediately on the close of the summer session, repaired to Görlitz for the purpose of examining the excavations now being made in that district.

MR. GEORGE SMITH of Coalville gave evidence on the 8th inst. before the Select Committee on the Temporary Dwellings Bill. He stated that about 30,000 children lived in vans and other temporary dwellings in the United Kingdom. These children went without education to an alarming extent, and their homes were almost totally outside sanitary influence. He doubted if more than 2 per cent. of this number could read and write, and not one in a thousand had any religious training.

LADY ROBERTS has issued a circular appealing for aid in behalf of the "Homes in the Hills" which have been founded for the benefit of the nursing sisters now employed in the British military hospitals in India. The appeal is accompanied by a statement explanatory of the scheme for supplying nurses for the hospitals.

WE regret to have to record the death of Gustavus Charles Philip Murray, M.D., which occurred on Sunday last at his residence, 66, Great Cumberland-place, Hyde Park, W. We hope next week to give some details of the life of the deceased physician.

MR. MARK HOVELL has been appointed to accompany the Crown Prince of Germany to Scotland, and to carry out the treatment prescribed by Dr. Morell Mackenzie.

REPORT
OF
The Lancet Sanitary Commission
ON THE
THAMES AS A WATER SUPPLY FOR LONDON.

MORE than half of the water supply of London is drawn from the Thames. Formerly a great deal was drawn from a foully polluted area in the heart of the metropolis, but, warned by the lessons taught by successive visitations of cholera, the intakes were removed to places above the tidal portion of the river. The five great Thames companies draw their supply just above Hampton and below Sunbury, while the East London Company is permitted to draw a further quantity not exceeding 10,000,000 gallons a day from a spot a little higher up, but below Walton. Altogether 110,000,000 gallons a day may be drawn from the river. During last May the quantity actually taken was 86,795,375 gallons. The whole of it is filtered and stored in covered reservoirs before delivery.

The question which we have to consider is whether this water, collected and treated with due care, is fit for the supply of the metropolis, or whether it is exposed to such serious pollution, either continuous or occasional and accidental, as to make it necessary to seek for a new supply. It is hardly necessary to remind our readers that the question is no new one. It has been keenly debated for a long time, and about twenty years ago a vast mass of new evidence was collected. Eminent scientific men took opposite sides in the controversy, and supported their views with experiments and arguments which have added greatly to our knowledge, and have stocked no small space in our libraries. Dr. Frankland, to whom we owe our most trustworthy method of water analysis, was then, and is, we believe, still foremost among those who consider the present supply dangerous, while Dr. Tidy, with the able assistance of Mr. Crookes and Professor Odling, have uniformly maintained the opposite view. It would be hopeless to attempt even the barest sketch of the literature of the subject; it is enough to mention that the matured views of Dr. Frankland were stated in the sixth report of the Rivers Pollution Commission (1874), which is a model of sound scientific work, while the case for the water companies was ably pre-

Digitized by Google

sented by Dr. Tidy in a paper published in the journal of the Chemical Society in May, 1880. Dr. Tidy's arguments, like those of Dr. Frankland, were supported by innumerable experiments, and there is no question of the accuracy of the analyses on either side. The Royal Commission on Water Supply, which reported in June, 1869, decided in favour of the present supply, provided, however, that efficient means were taken for the exclusion of sewage and other pollutions from the river and its tributaries. The commissioners, however, did not include in their number a single chemist or member of the medical profession, which detracts considerably from the value of their conclusion.

The present inquiry was of necessity limited in its scope. A full study of all the conditions which affect the purity of the water in the neighbourhood of the intakes was evidently impossible. But it was also unnecessary, for there is no dispute as to many of the facts, and in regard to others, illustrative cases are sufficient, because their typical character is self-evident. We selected for our study the region of the river which lies between the lowest intake, of the water companies just above Hampton, and Staines, a distance on the river of about eleven miles. Of course, we do not assert that no higher pollution is worthy of attention, but arguments founded upon it would be more open to objections, particularly to the well-known and important objection founded on the assumption that any pollution, however foul, is destroyed or rendered harmless in a flow of a few miles by natural oxidation assisted by living organisms, animal and vegetable. The assumption is a dangerous one, for it rests on no sufficient proof, and absolute proof would be required to justify its admission as a fact. We know that noxious matter is admitted into a river used as a water supply. We know also that sooner or later all noxious matter will be destroyed. But how long the process of destruction will take, what conditions are required for it, and what is the evidence by which its completion is proved are questions which cannot as yet be definitely answered. Noxious pollution above our London water supply is admitted by all, so that the burden of proof that it is harmless clearly falls upon those who assert that it is always and entirely destroyed before the water reaches the consumer. We presume, however, that no one would assert that excremental pollution only a few miles above a water company's intake involves no risk at all to public health.

Our recent inspection, by no means the first we have made in the same region, took place under peculiarly favourable conditions for the water. Long drought had reduced the river to a placid stream. Little water was passing over the weirs. Ditches and small tributaries were dry, and the river water was transparent and excellent in colour. Our observations and inquiries were made partly on land, but to a great extent in boats on the river, and we admit freely that if the water was as good as it looked, and could be kept so, it would, after efficient filtration, afford an excellent supply. Unfortunately, however, we were soon convinced that many and serious pollutions affected the river at all times, and that while all were disgusting, some were of a kind to constitute a permanent source of danger, especially in times of epidemic. It will save space if we classify the chief sources of pollution which we observed, offering a few remarks about each.

1. *Actual sewage.*—As far as we could discover there is very little actual sewage thrown from drains or privies directly into the river in the area under review. Our means of observation were limited, for of course we had no access to private grounds. The river everywhere is undoubtedly polluted, most seriously in its upper part, and the Bourne in its passage through Chertsey is a foul ditch which is certainly polluted. The Thames Conservators are, we understand, now using their powers to stop this defilement. The Abbey river, which runs close to Chertsey, is also, we believe, exposed to direct pollution, and we saw by the Willow-walk in Chertsey a foul ditch, almost empty at the time of our visit, which discharged through a grating into the river. At Staines it is admitted that there are one or two sewers that are in direct communication with houses and that the sewage passes in a raw state into the river. We were informed that very few houses are so drained, and that the town authorities are most anxious to disconnect them, but for the present the fact remains.

2. *House boats and barges.*—We have on previous occasions commented on the urgent danger to the London water supply occasioned by house boats and barges. It is true that the owners of house boats have recently been prohibited from defiling the river with their refuse, but who is to enforce the prohibition? Even if the owners are as particular as they ought to be, they cannot at all times supervise their servants, and are, moreover, often absent for days together. At night, especially, there must be frequent pollution, and who can say what character it bears? As to barges, there can be no doubt that the river, as it is the easiest, so it is the most common means of disposing of the excreta of the family. There were but few house boats or barges on the river at the time of our recent visit, but on previous occasions we have seen many. We do not know the amount of the barge population that travel by the intakes, but we believe it is considerable. The greatest danger arises of course at night, when the barges are moored. We have only to imagine a case of cholera occurring on a barge near Sunbury, or even farther up, to realise the danger.

3. *Bathing.*—It is impossible to estimate the number of persons who bathe in the river during the summer season, but it is certainly considerable. We have seen bathers below Sunbury Lock—that is, just above the great intakes. No one can blame the bathers, if they are allowed to bathe, but they certainly pollute the river in more ways than one, and it is not pleasant to think of drinking the bath water.

4. *Other pollutions.*—These may be best summarised in the words of the Rivers Pollution Commissioners (Sixth Report, p. 428): "The river is used for bathing, for the washing of sheep and cattle, and of dirty linen, and the putrid carcases of animals float upon its surface. It is the common waterway for a large amount of polluting matter, much of which is at times dangerous to the health of persons who use even the filtered water for dietetic purposes." We have little to add to this simple statement of fact. It is true that we did not see any dead dogs on our recent visits, but on previous occasions we have seen many, and on one occasion, about two years ago, we counted three swollen carcases between Hampton and Sunbury.

5. *Cesspools.*—The pollutions hitherto described are small in magnitude in relation to the volume of the river. It would be a great mistake to underrate the risk they involve; for we ought never to forget that the fearful outbreak of cholera in the East-end of London in 1866 was traced by Mr. Netten Radcliffe, after a careful inquiry, to two cases of cholera which had polluted the River Lea, and so the water of the East London Water Company. Nevertheless, they are small in comparison with the enormous pollution due to cesspools—a pollution the extent and significance of which has been greatly underrated. With a few exceptions, the whole of the excreta of the inhabitants of the Thames basin passes into cesspools. As to the majority of these cesspools, we have nothing at present to say, except that their constant proximity to wells involves perennial risk. But a large number of cesspools are close to the Thames or to the mouths of its tributaries, and many of these pollute the water supply of the metropolis in a serious and dangerous manner. Going up the river from Hampton, we find at Sunbury, Walton, Halliford, Shepperton, Weybridge, Chertsey, Laleham, and Staines, many houses, great and small, close to the water's edge. All these houses, or nearly all of them, drain into cesspools commonly sunk in very porous soil. The cesspools, we were repeatedly told, were slow in filling. One gentleman in Staines informed us that his had not been emptied for nine years, and we found at Weybridge, close to the mouth of the river, about six miles above the lowest intake of the water companies, a row of cottages where the cesspools were *within a few yards* of the river, and only required emptying once in three years. During flood times such cesspools fill rapidly, and as rapidly empty themselves into the river—that is, into the metropolitan water supply—when the flood abates. Staines is another notable example. The soil is low and porous, and the great majority of the houses are provided with cesspools. We were informed that the water rose and fell in these cesspools with the rise and fall of the river, but there can be no doubt that here, as elsewhere, along the banks of the river, the liquid portion of the sewage, most imperfectly filtered through a short layer of foul earth, finds its way into the Thames. There is now a public water supply for Staines, but there are still many wells, some of which are preferred by their owners to the new supply. We do not know whether this proves the inhabitants to be ignorant or the water supply bad.

6. *Floods.*—Another great cause of the pollution of the water supply is found in the floods which follow heavy rain. The action of floods in flushing cesspools we have already

Digitized by Google

described. But the influence of the flood is not confined to the cesspool and the sewer. Every dirty hole and corner is washed out by it; the manured field, the slaughter-house yard, the factory, the pigstye, and the dunghill alike contribute, and the foul muddy torrent pours into the London water supply. Dr. Tidy properly distinguishes between primary and secondary flood water—that is, between the earlier and later washings of the dirty earth. The former are much more objectionable than the latter; but all that concerns us is the obvious fact that both alike go into the reservoirs of the water companies.

It will be evident from what has been said that our latest study of the question has confirmed our previous opinion, so often expressed in these columns, that the Thames is at present, and is likely to remain, an unsuitable source of water supply for the metropolis. For the sake of distinctness we offer a summary of our conclusions:—

1. The upper Thames is a highway of commerce, a vast and increasingly popular pleasure resort for rich and poor, and the natural drainage channel for a district already highly populated and certain to become more populous year by year. 2. Although such a watercourse should for every reason be kept as pure as possible, it must always be exposed to so much continuous as well as casual pollution as to be a dangerous water supply for London. 3. Although much has of late years been done by the London water companies in improving their supply, particularly by more careful filtration, there is no proof that they can now or will ever be able to exclude from the water which they supply to London all matters injurious or dangerous to health. 4. In any case, the pollutions to which Thames water is necessarily exposed are of such a disgusting character as to render its use for drinking purposes undesirable.

While formulating the above objections, which seem to us undeniable, we wish to give prominence to all fair arguments which have been adduced on the other side. We admit fully that, as a general rule, chemical analysis fails to point out anything certainly deleterious in the water supplied by the Thames companies; but on this point we would desire it to be remembered that recent experiments for the Local Government Board have led to the conclusion that "we must [at any rate until other methods of recognition are discovered] go beyond the laboratories for evidence of any drinking water being free from any dangerous pollution." Furthermore, we admit that modern researches in bacteriology, among which those of Dr. Percy Frankland deserve honourable mention, have shown that filtration is a more potent agent in purification than was at one time supposed. But granting all this, we are still obliged to reiterate our opinion that the risks attendant upon the use of a water supply so foul, and increasingly so, as that of the Thames should not be lightly incurred by the largest and wealthiest city in the world. The experience of Lausen, quoted in the sixth report of the Rivers Pollution Commission, seems to prove beyond a doubt that the poison of typhoid may undergo what appears a very efficient natural filtration without losing its activity; and the history of the late epidemic of cholera in Spain, as told by Mr. George Higgin,[1] reminds us too forcibly of our English experience not to suggest fears that should not to be laid aside.

It will naturally be asked, What alternative scheme of water supply is offered if the Thames is to be abandoned? There are many alternative schemes, each of which would give us a safer and better water supply than we now possess. Our limits prevent us discussing them at present; but lest it should be supposed that they are merely dreams of sanguine engineers, we will quote once more, in confirmation, a passage from the Sixth Report of the Rivers Pollution Commission (page 430):—"Abundance of spring and deep-well water of excellent quality can be procured in the basin of the *Thames* and within a moderate distance of London; and we are of opinion that the metropolis and its suburbs should be supplied on the constant system exclusively with this palatable and wholesome water."

[1] Nature, June 17th, 1886.

FEVER HOSPITAL FOR DUNDEE.—It is proposed to erect a fever hospital in Dundee at a cost of £9000. At a meeting of the Sanitary Committee of the Local Police Commission on the 4th inst., plans of the hospital were submitted, and the Committee approved of the erection of two pavilions and part of the proposed administrative department.

VON PETTENKOFER'S LATEST VIEWS ON CHOLERA.

No living epidemiologist has dedicated more time or greater talent to the study of cholera than von Pettenkofer of Munich. Three years ago, after the outbreak of the disease on the Mediterranean seaboard, and when Koch's discovery of a comma bacillus was still recent, he wrote a series of papers on the theme, papers which were translated in full and published in THE LANCET. Since then a good deal of fresh light has been thrown on the subject, and von Pettenkofer has utilised it to supplement or reinforce what he had already given to the world. This "revised version" of his views has just been concluded in the *Archiv für Hygiene*, and we now offer our readers a succinct digest of the fourteen sections (*Abschnitten*) in which it is contained.

Having confirmed by additional proofs, drawn mainly from the experience of Persia and England, his demonstration of the worthlessness of quarantine afloat and *à fortiori* of inland cordons, he passes on to what may be called the "pilgrimage theory" of the diffusion of cholera. Here, again, he ranks himself with the sceptics, and shows, in a masterly summing-up of the evidence adduced by Bryden, Cuningham, and Bellew, that while pilgrimages, by the hardships and privations which attend them, undoubtedly predispose to the disease, they never convey it.

The vindication of these views occupies the first three sections of his treatise, and in the fourth he proceeds to estimate the practical worth of the comma bacillus of Koch. For the pathologist and clinician this, he admits, is of undoubted importance—mainly in the differential diagnosis between cholera nostras and cholera Asiatica. But for the epidemiologist and the hygienist in quest of prophylaxis it has little or no value. In the epidemics that ravaged Munich and Heilbronn in 1873, what, he asks, would have been the practical gain if the comma bacillus had been known then? Nothing; or as little as the tubercle bacillus proves in the treatment of phthisis. The infant science of bacteriology shows that nothing can be achieved against the diffusion of cholera by restriction of communication, however elaborate, because we can never make communication of any kind, least of all human communication, absolutely germ-proof (*pilzdicht*). To the bacteriologist, he says, in effect, it is no marvel that in any place whatever the best sterilised broth quickly presents germ growths, if the place has not been made hermetically germ-proof. If you put a broth in the most artistically prepared box, with as many bolts and bars as you please, a box whose fabrication, shutting and opening, costs no end of money and pains, the tyro in bacteriology can tell you beforehand that all your trouble is thrown away if the seclusion from germs is not absolute. The tiniest trace of a non-germ-proof chink will suffice to introduce the enemy, where it will always find its nidus. Meat, sterilised at a high temperature and kept in air-tight tin boxes, can make the tour of the world and arrive fit for consumption at its destination; but if an opening, invisible to the naked eye, admits to the interior of the box, the meat will get "high," even in a temperate climate. Had germ-proof cases been the *sine qud non* of fresh meat conservation, this would never have been a successful enterprise; but it succeeds by other means than the exclusion of germs. Slaughtered in Australia, meat arrives at the London market fresh, not by being sterilised or made germ-proof, but simply by being conveyed in ice chambers, and thus reduced by cold to a condition in which no bacteria can live or thrive. As the air everywhere carries putrefactive germs, so communication with cholera localities always and inevitably brings with it the germs of cholera. So long as the contagionist school fails to render every avenue of communication with cholera localities germ-proof, all their precautions count for nothing, all their restrictions of communication are worthless, and they must bethink themselves of some other means to keep human flesh (so to say) from corruption. On this and similar grounds von Pettenkofer also holds the isolation of cholera patients and the disinfection of their evacuations as of no use, and, in the two following sections, confirms his position by an elaborate induction of facts.

From his argument against the efficacy of regulations which are founded on the assumption that the infection of healthy subjects proceeds from cholera patients and their

Digitized by Google

excreta, von Pettenkofer comes to answer the question: "What, then, are we to do, if we admit free communication with the cholera-stricken, and assume that the infection proceeds from the cholera locality?" First, he takes into consideration the abandonment of the cholera locality itself—the so-called "cholera flight."

On grounds public as well as private he thinks it desirable that during an epidemic the population should abide on the spot, where, by personal care and management, they can protect themselves as thoroughly as if they had fled to another place; but still he is of opinion that cholera flight will always remain a practical question, to be dealt with practically. The magnitude of the flight depends on the intensity of the fear, and it is difficult to calculate whether this is greater if one assumes that the infection proceeds from the cholera patients (the contagionist view), or that it comes from the cholera localities (the localistic view). The fear, and the consequent flight can be prevented neither from the contagionist nor from the localistic standpoint; and in the case of persons who are not officially chained to the spot, we have no right to hinder them if they choose to go. That it is an effective prophylactic measure is proved, not merely in ships which leave an infected harbour for the high seas, where, as a rule, they remain exempt from the disease, or soon become so; but also in the abandonment of infected places on land, as is now practised successfully in British India in the case of all barracks and prisons as soon as cholera declares itself. The cholera flight is useless either when it is adopted too late, or when it is directed to a place which is also a focus of infection, or which becomes perhaps a worse quarter than that which is fled from. Having adduced most interesting illustrations from the movements of our garrisons in India, von Pettenkofer admonishes those who will and can run away not only to do so as soon as possible, but also to know whither they are going; for they might be exchanging "the frying-pan for the fire" (*aus dem Regen in die Traufe Kommen*). In this respect they will best be guided by the experience of former epidemics. On this subject and on the return of the cholera fugitives he gives a number of practical suggestions, and then passes on to show that, from the localistic standpoint (his own), cholera fugitives are not to be dreaded as importers of the disease. On this question he adduces a cogent array of facts all going to prove that cholera fugitives are freely to be acquitted of all charge of diffusing the epidemic, while only infections which are never more than exceptionally sporadic can be traced to them. If here and there, he says, the outbreak of an epidemic coincides with the arrival of a cholera fugitive, it is a case of casual coincidence merely, and the place would have been visited by the disease had no stranger come to it. How many thousands of fugitives in France since 1832 have fled from Marseilles and Paris to the cholera-exempted Lyons and Versailles without ever importing the epidemic? From cholera districts, he admits, one may here and there bring with him just as much of the locally-produced infective matter as may suffice to cause in another place a few sporadic cases; as, for instance, in 1854 an arrival from Munich occasioned three infections in the cholera-exempt Stuttgart, but these three produced no further infection, and the disease took no root. Besides, that any importation of the infective matter from cholera localities through travellers or fugitives can be prevented is shown by von Pettenkofer in a striking series of examples taken from the prisoners released from gaol in Laufen and Rebdorf during the last epidemic in Bavaria. While the disease prevailed in these two establishments there were ninety-four inmates set free, of whom each one, from the prison door to his permanent destination, and for more than six weeks, was followed by the police. These ticket-of-leave men, as we should call them, were scattered in the most various directions over Upper and Lower Bavaria, Swabia, and Neuberg, some even into the Upper Palatinate. *En route*, or on arrival at their destination, two of them fell ill of distinct asphyxial cholera, seven of cholerine and suspicious diarrhœas, but none of them died. These ninety-four fugitives, in fact, fared far better than the comrades they had left behind in their carefully superintended prisons, very many of whom died of the disease. Of these same ninety-four, moreover, of whom nine became ill outside the gaol, and who took the most diverse routes, not one communicated to the persons with whom for six weeks they were more or less in contact a single ailment bearing any resemblance to cholera. So, says von Pettenkofer, "from these two prisons we may learn how flight may be taken from a cholera district to the surrounding country without spreading the disease." And how were the prisoners set free? Only after a thorough bath, after laying aside every article they had worn within the walls, after getting fresh linen and clothes, and taking nothing with them from the establishment but a little money they had earned or saved. To these articles no infection could cling, in such quantity at least as to cause infection elsewhere; and as in the localistic view only the cholera locality and not the cholera patient produces the infective matter, so these nine patients outside the prison were unable, in the many places through which they passed and in which they sojourned, to communicate the faintest vestige of the disease. All the localities they came in contact with, several hundreds in number, remained free from cholera.

(To be concluded.)

THE PAIL SYSTEM AT MANCHESTER.

No. II.

IN dealing with the contents of the pails removed from the 66,000 ash closets of Manchester, the authorities have at least the advantage of treating a substance which does possess a commercial value. For many years the hope of deriving pecuniary benefit from the precipitation &c. of sewage water has been abandoned, but this is not the case with regard to the pail system. Nevertheless, this pail system, as worked at Manchester, is not managed on a commercial basis. Public health and public convenience are the first considerations; commercial advantages are relegated to a secondary position. It is needless to say that the working of the pail system has not been handed over to any private contractor, but is managed by the municipality of Manchester in the public interest. Such being the case, the first object held in view is not that of obtaining a concentrated and valuable manure, but of shielding the community from all nuisances or risks. If the commercial interests were paramount (and this would be the case should the enterprise be let out to a private contractor or a company), efforts might be made to prevent anything entering the pails except the soil. The municipality, however, justly conceive that such pails must occasion considerable nuisance; therefore, to deodorise their contents, it is arranged that the pails shall also receive the finer ash of each household. This ash is very effective in preventing bad odours; but, on the other hand, it greatly increases the difficulty and expense of converting the contents of the pails into a marketable form of guano. In this respect, therefore, there is a direct conflict between the interests of public health and the desire to realise financial profit. This situation points to the necessity of placing the management of all such works in the hands of those to whom money considerations are not of the first importance.

The pails are brought to the sanitary works, established by the municipality at Holt Town, Beswick, on the north-east side of Manchester. The prevailing winds would, we presume, not blow from the works towards the town. No sooner are the pails removed from the van than the lids are taken off, and the contents tilted over into a bottomless trough. Eight men are employed exclusively at this work, and it is calculated that each man empties about 1800 pails in a day. Other eight men seize and dip the emptied pails into a bath of water charged with a strong solution of carbolic acid. As a further precaution the bottom of each van is strewed to a depth of about half an inch with a carbolic acid powder; hence, if anything is spilt within the van, it falls on a disinfectant. Proceeding to a lower floor, we found that the soil, as discharged from the pails, falls on a revolving riddle from which there are two exits. On one side, the rougher materials, such as the larger pieces of cinder or any foreign objects accidentally thrown into the pail, fall on the ground. On the other side, the more liquid material is drained off into vats, whence it is discharged into a concentrator that holds 480 gallons. Here it is mixed with eight gallons of sulphuric acid, and heated to 230° F., under a pressure of 40 to 50 lb. of steam.

From the top floor, forty feet above, a twelve-inch pipe discharges water upon the gases evolved from the concen-

Digitized by Google

trating machines. This naturally dissolves all soluble gases; further, these gases, passing away from this washing tower, are conducted into a flue placed in connexion with the thirteen boilers established on the works. These nearly suffice to consume all the organic matter, and convert it into water and carbonic acid. Nevertheless, the Health Committee of Manchester are not satisfied with this process, and now purpose to construct a chamber for the special purpose of receiving these gases and exposing them to a temperature varying between 1000° and 1500° F. This would ensure the absolute destruction of all detrimental organic matter.

The contents of the pails, when dried in the concentrators and converted into guano, possess, during the summer time, about 2·75 of ammonia and 3 per cent. of phosphates. Mr. C. Kilpatrick, the chemist in charge of the works, who ably described the whole process to us, explained that he analysed the guano every day, and added the required amount of phosphates and ammonia, so that the manure might always possess a uniform standard of strength and value. This is set down at 30 per cent. of organic matter, including 3 per cent. of ammonia and 8 per cent. of phosphates, thus generally entailing an addition of ½ per cent. of the former and 5 per cent. of the latter. Unfortunately for the success of this enterprise, the value of ammonia has greatly fallen of late years. In 1879, it was sold at from 18*s.* to 20*s.* per unit; whereas now it is only worth from 9*s.* to 10*s.* the unit. During the last year 16,200 units of ammonia were sold, and this at 10*s.* would only realise £8100, while six years ago the amount recouped by the municipality to defray its expenses would have equalled £16,200 for ammonia alone.

Fortunately the efforts of the municipality in other directions have met with greater success. The refuse from the slaughter-houses, the condemned fish, &c., are all brought to the sanitary works and advantageously utilised. In this animal boiling department a net profit of £500 a year is secured. The grease obtained is used in a variety of ways. A considerable saving is realised by employing it to lubricate the machinery. Then a portion is turned into soap mixed with carbolic acid, and given away for the purpose of washing premises after disinfection, &c. The soap is doubtless good chemically. It contains, we believe, 60 per cent. of fat and 8 per cent. of carbolic acid; but we must enter a protest against its abominable odour. The love of cleanliness and the appreciation of sanitary precaution will not spread among the people by the distribution, even gratuitously, of such offensive soap. The odour is undefinable, but it is powerful and sickly. Surely some improvement is possible. Among the various experiments that have been made in this department, may be mentioned the utilisation of the oil extracted from the fish that are destroyed, for the purpose of mixing with paint. When thus prepared, it is found that the paint dries much quicker. Mr. Kilpatrick is also seeking to volatilise the fish oil so as to make gas, which, he expects, will be superior in some respects to coal gas. Finally, we should not omit the great demand for dog fat. When a sufficient number of dead dogs can be collected, it pays to empty and clean one of the boiling vats so as to employ it exclusively for the extraction of dog fat. This fat can be sold at a comparatively high price.

The Holt Town Works are conveniently situated by the side of the Ashton Canal and the Lancashire and Yorkshire Railway. This position enables the managers to deliver the guano free of charge for carriage to a distance of fifty miles. Including sacks, in which it is packed, the manure is sold actually at £3 the ton, and has been extensively patronised by agriculturists in a variety of districts. The works of Holt Town occupy an area of 29,470 square yards; they cost to erect £130,000, and there is, besides, a chief rent of £737 15*s* 6*d*. Roughly speaking, some 250 tons of closet and other refuse are treated daily; and by burning and evaporation they are reduced to half their original weight. At the same time, they are converted into inoffensive material. The operation, however, is far from being inoffensive. We are not prepared to say that the stench is injurious to health, but it is certainly highly objectionable, and it pervades not only the works, but the whole neighbourhood. It is indeed most unfortunate that so many habitations should be so close at hand. The works stand between the boundaries of the townships of Manchester and of Beswick. In the nearest sub-sanitary district of the former we find the area is estimated at 44 acres with a population of 73 persons to the acre; but, if we take only the portion covered by occupied houses, the population is equal to 192 per acre. On the Beswick side it is about 90 per acre. In the part of Manchester where there is the most crowding, the population is equal to 234 persons per acre. These figures will show that the works are not far enough removed; and, when they were constructed, better account should have been taken of the growing propensities such a centre of industry was likely to manifest. Throughout the works, little saucepans, containing a solution of carbolic acid, are kept perpetually boiling over gas jets. How far this suffices to disinfect the emanations arising from heating and drying so much manure we are unable to say. One fact must be noted: the two nearest districts, Ancoats and Beswick, have, during the last two years, shown the highest death-rate of all Manchester. This may be due to many other causes, but it is, nevertheless, a sufficiently ominous symptom to awaken attention.

On the premises of the Holt Works everything is manufactured that is connected with the application of the pail system. For this various descriptions of labour are required. There is a sewing-room, for instance, where young women are employed making the bags for packing the manure and other articles. Some of these women, we find, are only paid 8*s.* a week, though they have to work, to say the least of it, in a very unpleasant atmosphere. This may be the competition rate of wages. Indeed, distress is so prevalent that women might possibly be obtained to do the work for even less. This is, however, a public institution, established for the public good, to preserve the public health; and though 8*s.* may be the competition rate of wages, we maintain that it is not a sanitary rate of wages. It is impossible for a woman to lodge, feed, and clothe herself decently on 8*s.* a week. To the honour and credit of Manchester, be it said, the manufacture of manure is not conducted on a strictly commercial basis. If, then, public health is first considered, why not also the health and comfort of the individuals who work at the depôt itself? The men earn at least from 4*d.* to 5*d.* an hour, the horsemen and carters 24*s.* a week, and the carriers 20*s.* a week; and there are, in all, 420 men employed at the Holt Works. We are not aware that women can live healthy lives on a much smaller sum than men. It would make but an imperceptible difference in the general outlay if public institutions were in such cases to set a better example.

The tinmen who make the pails receive 7½*d.* per hour, and the value of each pail is estimated at 6*s.* The lid is worth 5*s.*, but one lid suffices for two pails. Round the lid there is an indiarubber tubing, so that when pressed down the pail is hermetically closed. It has been found that these pails will last about ten years, therefore we may conclude that the pails cost a shilling per year each. They are made with sheets of galvanised steel, and are very handy and convenient in shape. The only complaint we heard concerning the pails arose from the carelessness of some persons, who, instead of reserving the pails exclusively for the night-stools and the fine ash, occasionally throw miscellaneous rubbish into them. This complicates matters a little for the men who empty the pails, but does not endanger in any way the sanitation of the town.

In conclusion, we should note that the entire cost of the nightsoil department amounted for last year to £106,886 10*s.* 10*d.*, to which should be added £4248 paid for liquidation of debt, giving a grand total of £111,132 10*s.* 10*d.* Against this must be set the total receipts derived from the sale of manure, mortar, bricks, and other things made out of the refuse; this amounted in all to £57,546 4*s.* 4*d.* Thus, the net expenditure for Manchester, with its population of 385,678 persons, only amounted to £49,340 6*s.* 6*d.*, and £4246 towards liquidation of previous debts. In spite, therefore, of the exceptional depreciation in the value of ammonia, the receipts covered more than half the total expenditure—a result which compares most favourably with water-carriage drainage, where it is all expenditure and there is no income.

Taking these circumstances into account, the town of Manchester may be warmly congratulated on the course it has adopted and the valuable example it has given. The experience acquired in this great manufacturing centre will be most useful to other communities, and will suggest a practical solution in many instances where objections are raised to the ordinary methods of drainage.

DETERIORATION OF PHYSIQUE IN THE POPULATION.

IN his address as Vice-President of the Public Health Section of the British Medical Association, Sir Thomas Crawford, while admitting as one of the results of sanitary science a "perceptible prolongation of life," expressed his opinion that this was attended with "a perceptible deterioration or degradation of life in the lower order of people." This view he supported by reference to the results of the medical examination of recruits for the army, which in the quinquennium 1860-64 showed the rejections to have been only 372 per 1000 inspected, while in the five years 1882-86 they were 416 per 1000. "A careful examination of these tables led to the inference that the lower class, from whom the recruits for the army are chiefly taken, are of an inferior physique now to what they were twenty-five years ago." But while we reluctantly differ from so high an authority as Sir Thomas Crawford on military medical questions, a study of the tables in the Army Medical Department Reports has brought us to a very different conclusion. Before, however, stating the results of our investigation, it is necessary to call attention to two points which have an important bearing upon the comparison. First, in the four years 1860-63 the returns of recruits include those only who were examined at the head-quarters of districts, and secondary inspections are included in the general result with primary, which must obviously reduce the proportion of the rejections. It was in 1864 that the inspections at regiments and at depôts, and by civil practitioners, were first included in the returns. It must be obvious, therefore, that in any comparision with later periods the early defective years must be omitted. Secondly, owing to a change in the regulations, the decision upon certain disqualifications, which had previously been the duty of the recruiting officer before the recruit was sent for inspection, was transferred to the medical officer. The two most important of these were the height and the *apparent* age of the recruit. In the first five years referred to there was not a single rejection under either of these heads, while in the four years 1881-4 they averaged 2434 annually, or 44·4 per 1000 of recruits inspected. Sir Thomas Crawford included in his statement the returns to the end of 1886, but as the last published volume of the department reports is that for 1884 we are unable to make the comparison, with these corrections, to the later date. Taking as a basis, however, the four years 1864-7 and the four 1881-4, and deducting from the latter the rejections for height and age, and a few found "unfit within three months of enlistment," who are obviously not rejected recruits, but discharged young soldiers, we obtain the following results: In the four years 1864-7, of 99,701 recruits inspected, 40,873 were rejected, or 410 per 1000; while in the four years 1881-4, of 219,185 inspected, the rejections, exclusive of the three groups noted, were 81,023, or only 370 per 1000. If, then, the results of the examination of recruits may be taken as a measure of the physique of that class of the population from which they are drawn, there has apparently been an improvement instead of a deterioration. But we entertain strong doubts of its being at all a correct measure; between the two periods a very marked change was made in the constitution of the army, by which the number of recruits required for it was more than doubled. The necessity for this increase, added to greater facilities for invaliding men when found unfit, may very probably have led to some relaxation in the inspection, particularly with regard to some of the minor disabilities, and the state of the labour market may have exerted a considerable influence upon the class of men who presented themselves for enlistment. So far, however, as the returns bear on the question of the physique of the people, they certainly do not sustain the view advanced by Sir T. Crawford. There appears to be a somewhat widespread opinion that because the effect of sanitary improvement is shown chiefly in the reduction of infant mortality, therefore the result is obtained by the introduction into the population of a class of beings of inferior physical powers, who but for the removal of the active causes of disease would have fallen victims to them. But it seems to us that the changes which saved them must have had an important influence in improving the other classes, and that these saved lives merely take the place of the others in the physically lowest class, but that they are not necessarily inferior to those whose place they have taken in the scale of society, and who have been raised to a higher health platform as a result of the same measures.

THE USE OF BORACIC ACID AS A FOOD PRESERVATIVE.

To the Editors of THE LANCET.

SIRS,—The question of boracic acid as a so-called food "preservative" being one of public interest at the present time, I beg herewith to enclose you a full translation I have made (from the German) of Dr. Förster's views, as incidentally and partly referred to in the joint report presented by Mr. Cassal, F.I.C. (our public analyst), and by Dr. Dudfield (medical officer of health), at the last meeting of the Kensington vestry.—I am, Sirs, yours obediently,

CHARLES HANCOCK,
Member of Parkes Museum and of the Kensington Vestry.

Aug. 7th, 1887.

[TRANSLATION.]

Memorandum from Dr. Dingler's "Polytechnisches Journal" for the year 1884, p. 170, upon the Use of Boracic Acid as a so-called Food Preservative.

"As Professor J. Förster, in the journal of the proceedings of the German Chemical Society, points out, the applicability of the so-called antiseptic compounds for the preservation of food and drinks does not alone depend upon how far the same may be safely taken into the human body without any clearly noticeable results arising therefrom, such as those caused by doses of medicine, but it also depends upon what effect the use of the above named acid may produce if used as an addition to food and drink, especially if by its use a different operation takes place in the intestines, under the influence of the preserving salts, than would be the case were the ordinary food consumed in an unpreserved state; and should the effect be injurious, then it will become a question as to whether its use should not be restricted. Now, two classes of experiments have been made as to the effect of boracic acid if added in small quantities to daily food—first, on a so-called mixed diet; and secondly, on a diet consisting exclusively of milk and eggs. For three consecutive days nourishment was taken in the form of milk, bread, vegetables, &c., which analysis showed to contain the following: 475·7 grms. (dry substance), 17·33 grms. (nitrogen), 140·4 grms. (fat). Again, of the food taken and afterwards evacuated as fæces, as regards dry substance and nitrogen respectively the results were as follows:—

		Dry substance (*Trocken substanz*).	Nitrogen (*Stickstoff*).
Class 1.	Exp. 1: without bor. acid ...	12·4%	20·0%
,,	Exp. 2: with 3 grms.	14·8	23·9
,,	Exp. 3: without bor. acid ...	14·2	22·5
Class 2.	Exp. 1: with 1·5 grms. ...	6·2	4·2
,,	Exp. 2: without bor. acid ...	5·2	3·1
,,	Exp. 3: with 0·5 grms. ...	5·8	4·0
,,	Exp. 4: without bor. acid ...	4·6	3·0

Summing up the result of both classes of experiments, there can be no manner of doubt that the addition of boracic acid as a preservative—even in small doses, such as would not produce general or pharmaco-dynamic (*Pharmakodynamische Wirkingen*) effects in the human body—has an influence upon the digestive organs of man. This influence shows itself, too, in this: that it has been proved that the expulsion of fæcal matters, especially of those containing dry substance and nitrogen—even if only by a little—is, at all events, thereby increased. It is worthy of note that the effect of boracic acid can be distinctly recognised in the intestinal discharge, even after the addition of only 0·5 grm. in one day; while such discharge takes place in proportion to the quantity of the acid taken into the system, the effect continuing for some time after the acid is no longer added to the food. Further, it is of importance to point out that the influence can not only be noticed in a mixed food diet consisting of animal and vegetable matter, which in itself already contains a great deal of indigestible sub-

Digitized by Google

stances, but even in the consumption of milk and eggs, which, according to the most varied experiments, become digested and absorbed (*resorbirt*) in the intestines, with the exception of a few particles on which the digestive juices have no effect. It may be explained thus: That the introduction of boracic acid into the intestinal canal is followed by an increased secretion of the digestive juices, and consequently the dry substance contained in the fæces becomes increased by reason of the fact that the normal residua of the intestinal juices are more abundantly supplied. On the other hand, it is quite possible that a lesser quantity of component particles of food—especially of nutritive substances, properly speaking—(if containing boracic acid), would be absorbed in the intestines, or even that on their way to the intestinal canal they might become mixed up with a large quantity of solid matters—e.g., *thin layers of epidermis* from the mucous intestinal membrane, or something of that kind in a normal state; and thus the quantity of fæces would be increased. The first-mentioned effect might be considered a favourable one; but in the latter two cases—i.e., decreased absorption or increased repulsion of cellular matter from the mucous membrane of the digestive canal would without doubt result in effects of an injurious character, effects which in the case of frequently repeated or continuous uses of the drug would in course of time be followed by evil consequences. Fæcal matter impregnated with boracic acid seems to differ hardly, or at all, in respect of water, nitrogen, mineral matter as well as of neutral fats and free fatty acids found in it, from normal fæces—that is to say, when the nutriment taken is the same. On the other hand, the quantity of the substance extracted is decidedly larger (containing as it does nitrogenous elements of decomposition appertaining to the digestive juices and fat acids, obtained by submitting, by means of an acid containing alcohol, to analysis those fæcal matters discharged as the result of a diet of milk to which boracic acid has been added) than the substance extracted from the ordinary milk fæces evacuated under similar conditions. At the same time in the ordinary milk fæces there is much less nitrogenous matter which is not dissolvable by any known process of analysis than is the case with the fæces obtained from a diet of milk and eggs to which boracic acid has been added. Consequently, the addition of the acid to food leads on the one hand to an increased secretion of bile, but on the other, what is of infinite importance, to an increased discharge of albuminous matter from the intestinal canal—matter which for the most part probably owes its existence in the system to the food consumed. This last-mentioned effect, operating upon the human intestines, must certainly be looked upon as anything but a desired one. Accordingly, boracic acid is not suitable as a food preservative to the degree people are inclined to think, but especially careful ought one to be as regards adding it to milk intended for the nourishment of infants."

THE NEW SYDENHAM SOCIETY.

The twenty-ninth annual report of this Society was presented at the meeting of the members on the 5th inst., from which it appears that during the year 1886 the following four works were issued:—1. A volume of Essays on Micro-parasites in their relation to special diseases. The essays constituting this were translated from French and German sources. 2. The twelfth fasciculus of the Lexicon of Medical 3. Dr. Creighton's translation of Prof. Hirsch's of Geographical Pathology and Histology was by the issue of its third volume, in December. February, 1887, the series for 1886 was concluded by of the thirteenth part of the Lexicon of Medical which brought the work up to near the end of the

The following works will constitute the series for the 1. The first volume of Spiegelberg's Mid- by Dr. Hurry (now in course of issue). fasciculus of the Society's Lexicon of 3. The sixth fasciculus of the Atlas of Diseases of the Liver and Calculi. of selected Monographs, comprising Raynaud's Disturbances of Circulation in the Extremities (Asphyxia of the Extremities), translated by Dr. Barlow. Klebs and Tommasi-Crudeli on the Nature of Malaria. Marchiafava and Celli on the Blood in Malaria-Infection, and on the origin of Melanæmia (Dr. Drummond of Rome). Neugebauer's Essay on Spondylolisthesis. Litzmann on Labour with Contracted Pelvis. Bandl on the Changes which occur in the Uterus and its Cervix during Pregnancy and Labour. Litzmann on Rupture of the Uterus and the Mechanism of its Occurrence. 5. Clinical Lectures on Diseases of the Nervous System, by Professor Charcot; translated by Dr. Thomas Savill.

The following are the works which, in addition to the above, are in preparation:—1. The second volume of Spiegelberg's Midwifery, to be probably the first issue for 1888. 2. Flügge on Micro-parasites; to be translated by Mr. Watson Cheyne. 3. A volume of Translations and Abstracts from the works of Professor Fournier. 4. A seventh fasciculus of the Atlas of Pathology, to comprise Diseases of the Brain and Spinal Cord. 5. Cohnheim's General Pathology; to be translated by Dr. McKee. 6. A volume of selected Monographs, chiefly from German sources.

From the financial report it appears that the receipts for the year amounted to £2718, and that a balance of £129 remained in the hands of the treasurer.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Batley Urban District.—This is an important and increasing district, where proper sanitary administration will effect much ultimate good. There are now no means of isolation, and this although the zymotic death-rate is decidedly above the average; and Dr. Swann distinctly tells his authority that infectious diseases must remain endemic until the sanitary arrangements of the place are much more advanced. Diarrhœa is one of the prevailing causes of death, and it must be largely ascribed to conditions favouring sewer pollution of air. Unfortunately the antiquated and foul midden privy widely prevails, leading to pollution of surrounding air and to soakage of soil. Disconnexion of house drains from the sewers is also much needed. These conditions call for energetic dealing with existing nuisances, and for preventive action by means of proper bye-laws regulating such matters. Some substantial progress is being made, and the town has fortunately an excellent and abundant water service. The general death-rate during 1886 was 19·6 per 1000 living.

Nottingham Urban District.—Dr. Whitelegge is able to open his annual report for 1886 by the satisfactory declaration that considerable sanitary progress was made in the borough during the year. The town has attained to the rank of fifth amongst the large English cities and towns in point of death-rate; preparations are in progress for the erection of a new fever hospital; disinfection is carried on efficiently on an ever-increasing scale; paving, sewering, and widening of streets are steadily in progress; and whilst back-to-back houses are on the increase in many of our northern towns, we are glad to read that in Nottingham this class of dwelling, which is incapable of proper through ventilation, is constantly diminishing in number. Together with such work there is a distinct saving of life, especially under such headings as typhoid fever, phthisis, and diarrhœa. The annual death-rate from all causes now stands at 18·9 per 1000, having fallen from an average of 21·2 for the eight years 1878-85; the population having in the meantime increased from about 172,000 to 233,000. The advantages of the system of compulsory notification of infectious diseases are still maintained, and they were last year exemplified in the case of enteric and scarlet fevers. Inhabited vans, cowsheds, dairies, slaughterhouses, and offensive trades are well kept under supervision, and inspection of food supplies is maintained.

West Kent Combination.—For the seven rural and five urban districts included in this combination, the general death-rate during 1886 was 15·8, and the zymotic rate 1·36 per 1000 living. The smallest rate from all causes was 11·6 in the Beckenham urban district; the largest was 18·8 in

Digitized by Google

the Tenterden urban district. Separate reports have reached us as to several of these districts.—*Bromley Rural District:* The death-rate for this district was 14·4 per 1000 in 1886, as opposed to an average of 15·2 in the preceding ten years. Two deaths from diphtheria occurred in one house at Chelsfield; but Dr. Butterfield believes no other cases took place in his district. As an instance of the sort of disease that gets placed under the Registrar-General's heading "cholera," a case may be noted that occurred at Farnborough, where an old lady in her eightieth year died after taking six aperient pills, followed by a luncheon on cucumber. Unfortunately the dearth of water in parts of this district remains unremedied since the throwing out of the West Kent Company's Bill in 1885.—*Sevenoaks Urban District:* Here the death-rate was 14·8, and the zymotic rate only reached 0·7 per 1000 during 1886. But Dr. Butterfield expresses the conviction that the lives of infants are sacrificed to the unwillingness of mothers to supply their offspring with the natural breast milk, and he urges lady visitors to instruct and advise mothers properly in this respect. No case was admitted into the fever hospital, simply because no cases needed such isolation.—*Sevenoaks Rural District:* In this portion of Dr. Butterfield's district the death-rate was 16·5 per 1000 last year, the zymotic rate being 1·6. Among the latter, small-pox, measles, and diarrhœa were most prominent; and a special report is appended on the subject of small-pox at Edenbridge, the workhouse, and Hever. At the former place railway works were in progress, and the disease was imported through the navvies employed.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5208 births and 4050 deaths were registered during the week ending August 6th. The annual rate of mortality in these towns, which had increased in the preceding six weeks from 17·6 to 23·2 per 1000, declined again last week to 22·9. During the first five weeks of the current quarter the death-rate in these towns averaged 21·7 per 1000, and was 0·6 above the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 13·2 in Brighton, 16·0 in Birkenhead, 17·1 in Halifax, and 17·5 in Bristol. The rates in the other towns ranged upwards to 27·8 in Huddersfield, 29·6 in Newcastle-upon-Tyne, 30·3 in Wolverhampton, and 39·3 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the preceding five weeks from 486 to 1301, declined last week to 1293; they included 973 from diarrhœa, 125 from whooping-cough, 93 from measles, 54 from scarlet fever, 30 from "fever" (principally enteric), 17 from diphtheria, and only one from small-pox. These zymotic diseases caused the lowest death-rates last week in Halifax and Cardiff, and the highest rates in Manchester, Sheffield, Leicester, and Preston. The highest death-rates from diarrhœa occurred in Derby, Portsmouth, Sheffield, Nottingham, Leicester, and Preston; from measles in Bolton, Manchester, and Oldham; from whooping-cough in Birmingham; and from scarlet fever in Blackburn. Of the 17 deaths from diphtheria in the twenty-eight towns, 7 occurred in London, 2 in Liverpool, and 2 in Portsmouth. Small-pox caused 1 death in Sheffield, but not one in Greater London, or in any of the twenty-six other large provincial towns. Only one case of small-pox was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding five weeks from 199 to 160, further fell last week to 158, and were 84 below the corrected average. The causes of 104, or 2·0 per cent., of the 4050 deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Plymouth, Bolton, Blackburn, and Cardiff; the largest proportions of uncertified deaths were recorded in Oldham, Norwich, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·9 and 19·9 per 1000 in the preceding two weeks, further declined to 17·1 in the week ending August 6th; this rate was as much as 5·8 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 10·6 and 15·8 in Aberdeen and Leith, to 21·1 in Perth and 28·2 in Paisley. The 428 deaths in the eight towns last week showed a further decline of 59 from the numbers in the preceding two weeks, and included 28 which were referred to diarrhœa, 22 to whooping-cough, 9 to "fever" (typhus, enteric, or simple), 7 to scarlet fever, 6 to diphtheria, 1 to small-pox, and not one to measles; in all, 73 deaths resulted from these principal zymotic diseases, against 103 in each of the preceding two weeks. These 73 deaths were equal to an annual rate of 2·9 per 1000, which was 4·3 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 39 in each of the previous two weeks, declined last week to 28, of which 13 occurred in Glasgow, 6 in Dundee, 3 in Edinburgh, and 2 in Leith. The deaths from whooping-cough, which had been 37 and 41 in the preceding two weeks, declined last week to 22, and included 11 in Glasgow and 5 in Dundee. The 9 deaths referred to "fever" exceeded by 5 the number in the previous week; 6 occurred in Glasgow and 2 in Edinburgh. The fatal cases of scarlet fever, which had been 5 and 12 in the previous two weeks, declined last week to 7, and included 5 in Dundee. The 6 deaths from diphtheria showed an increase of 3 upon the number in the preceding week, and included 4 in Edinburgh. The fatal case of small-pox occurred in Aberdeen. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 82 and 65 in the preceding two weeks, were 67 last week, and 7 above the number returned in the corresponding week of last year. The causes of 56, or 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had increased in the preceding four weeks from 26·6 to 30·9 per 1000, declined to 29·6 in the week ending August 6th. During the first five weeks of the current quarter the death-rate in the city averaged 29·0, the mean rate during the same period being but 22·6 per 1000 in London and 19·0 in Edinburgh. The 200 deaths in Dublin last week showed a decline of 9 from the increasing numbers in recent weeks; they included 29 which were referred to diarrhœa, 16 to measles, 4 to scarlet fever, 3 to whooping-cough, 2 to "fever" (typhus, enteric, or simple), 1 to diphtheria, and not one to small-pox. Thus the deaths resulting from these principal zymotic diseases, which had been 48 and 49 in the preceding two weeks, further rose last week to 55, owing to the increased prevalence of summer diarrhœa, and were equal to an annual rate of 8·1 per 1000, the rates from the same diseases being 7·4 in London and 2·4 in Edinburgh. The fatal cases of diarrhœa, which had been 21 and 16 in the preceding two weeks, rose again last week to 29. The deaths referred to measles, which had been 21 and 22 in the preceding two weeks, declined to 16, a lower number than has been recorded in any week since May last. The 4 fatal cases of scarlet fever showed a further increase upon recent weekly numbers, while the 3 deaths from whooping-cough corresponded with the numbers in the preceding week. The deaths of infants showed a decline from the high number in the previous week, while those of elderly persons showed an increase. Two inquest cases and 2 deaths from violence were registered; and 38, or nearly one-fifth, of the deaths occurred in public institutions. The causes of 28, or 14 per cent., of the deaths registered during the week were uncertified.

THE SERVICES.

YEOMANRY CAVALRY.—Warwickshire: Surgeon T. W. Bullock is granted the honorary rank of Surgeon-Major (dated Aug. 6th, 1887).

ARTILLERY VOLUNTEERS.—4th Volunteer (Cinque Ports) Brigade, Cinque Ports Division, Royal Artillery: Acting Surgeon Otho Robert Travers is appointed Second Lieutenant (dated Aug. 6th, 1887).

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Prince of Wales's Volunteers (South Lancashire Regiment): Surgeon J. H. Gornall resigns his commission (dated

Aug. 6th, 1887).—Honorary Assistant Surgeon J. W. Watkins, M.D., to be Surgeon (dated Aug. 6th, 1887); Surgeon J. W. Watkins, M.D., is granted the honorary rank of Surgeon-Major (dated Aug. 6th, 1887).—16th Middlesex (London Irish): Philip Percival Whitcombe, M.B., to be Acting Surgeon (dated Aug. 6th, 1887).

Correspondence.

"Audi alteram partem."

THE SALICYL COMPOUNDS IN ACUTE RHEUMATISM.

To the Editors of THE LANCET.

SIRS,—In the address in medicine delivered at the meeting of the British Medical Association in Dublin the other day, Professor Gairdner made the remark that "the benefit derived in acute rheumatism from the salicyl compounds is very satisfactorily established." In the same number of THE LANCET, in which this remark appears, Mr. Greene of Wallingford reports a case of acute rheumatism in which salicin and salicylate of soda are stated to have "failed to exercise their so-called specific action."

Mr. Greene's case is a type of a number of similar ones which have been published of late years, all pointing to the same moral—the inefficiency of the salicyl compounds. As the most recent one of the kind, and one of the best reported, I shall, with your leave, take Mr. Greene's case as a text on which to found a few remarks on the subject with which it deals; this not for the sake of criticising Mr. Greene's very interesting case, but solely with the object of indicating and insisting on a point of much practical importance in the treatment of acute rheumatism.

On June 18th Mr. Greene's patient had pains in the limbs and joints, and some febrile disturbance. Nothing is said regarding treatment then. On the 21st there was considerable pain and swelling of the wrists, finger-joints, and ankles, and also profuse perspiration, having the characteristic rheumatic odour. The temperature was 103° and the pulse 120. The patient got twenty grains of salicin every three hours. This was continued for a week, during which time the temperature was fluctuating, but rarely rose higher than 102°, and the joint complications and rheumatic perspirations continued. On the 28th the temperature rose to 103°, and there was much restlessness. Salicin was given every two hours in twenty-grain doses. On the 29th the temperature rose to 106°, and in a few hours to 107·4°; the pulse was small and irregular, the face livid, and the patient delirious. The case had become one of rheumatic hyperpyrexia, and the patient was in imminent danger. The cold bath and ice to the nape of the neck were had recourse to with excellent results, and by judicious management a very alarming illness was brought to a favourable termination.

Such is a brief summary of the salient points in Mr. Greene's case. The special point with which I would deal is his assertion that the salicin failed to exercise "its so-called specific action." The facts as stated by Mr. Greene apparently quite bear out this assertion. The patient did get salicin regularly for a week, and the salicin failed to check the rheumatic process. "From June 21st to June 29th," says Mr. Greene, "my patient had taken at least 1280 grains of salicin, and in spite of this the temperature had risen to 107·4°." That is a perfectly accurate statement, and apparently a very telling one against the salicin, and quite justifying Mr. Greene's indictment. But only apparently, for what does it really mean? 1280 grains in eight days are 160 grains a day, or 6·6 grains an hour, a totally inadequate dose. As well might one give a man suffering from intermittent fever one grain of quinine every three hours, and say that the quinine failed to exercise its so-called specific action, as it certainly would in that dose. From the time that I first introduced salicin to the notice of the profession as a remedy in acute rheumatism in your pages (now more than eleven years ago), I have never ceased to insist that small doses are of no use, and that to get its full beneficial action the drug must be given in large and frequently repeated doses. In my book on Rheumatism, published in 1881, this point is thus referred to (p. 199): "To get its full beneficial effects, the remedy (salicin) must be given in full and frequently repeated doses. ....., Twenty to forty grains should be given every hour till there is decided evidence of its action. It will generally be found that before an ounce has been consumed, often before half that quantity has been taken, there is a marked improvement. ..... As the symptoms decline the dose may be diminished; but it is well not to do this too quickly or too early, for if the remedy be omitted too soon, or given in inadequate dose, the symptoms are apt to recur." The salicyl compounds are very rapidly eliminated from the system, and their full beneficial action in acute rheumatism can be got only by frequently repeated full doses. Mr. Greene's patient never had the chance of being under the influence of salicin; the twenty grains which he got at 12 o'clock had probably nearly all passed off from the system before the 3 o'clock dose was given.

I hope I have said enough to show that Mr. Greene's facts do not warrant his charge of failure against the salicyl compounds. I do not think that I exceed my right when I ask those who criticise the action of these drugs, with which my name is associated, to give them in that dose which I insist upon as essential to the production of their full beneficial effects.

One word on rheumatic hyperpyrexia. Hyperpyrexia is not a part of the rheumatic process. It is to be regarded as an accidental complication which may occur in any form of fever, but is most common in acute rheumatism. It is probably due to some idiosyncrasy on the part of the patient—some weakness or unusual susceptibility of the heat regulating apparatus in the nervous centres. In rheumatic hyperpyrexia the salicyl compounds, so potent in rheumatic pyrexia, are of no use. In that condition cold to the surface is the one effectual remedy. It cannot be too clearly stated that it is mere waste of valuable time to have recourse to any other treatment.

I am, Sirs, your obedient servant,

Cadogan-place, Aug. 7th, 1887. T. J. MACLAGAN, M.D.

THE ARMY MEDICAL DEPARTMENT.

To the Editors of THE LANCET.

SIRS,—At page 270 of THE LANCET of August 6th, 1887, you say, "The *plébiscite* of the army medical officers we consider an unwise and unwarrantable act, it cannot but be an undeserved reflection on its [the department's] head."

As one of the army medical officers who received the paper you call a *plébiscite*, I desire to enter my protest against such a statement. The document was regarded, both by myself and by all I spoke to on the subject, as a mere request by the journal to be favoured with individual opinions on the subjects mentioned. I am sure Sir Thomas Crawford would be the last man in the world to consider that an army medical officer expressing an opinion in a medical journal, even if that opinion were not in accord with his own, could be an undeserved reflection on his opinions, it would be a *reductio ad absurdum*. I took care, however, to head my remarks with the statement that these were my opinions, and as such might be right or might be wrong. But I had the courage of my opinions, and the editor was quite at liberty to publish my name, which I now subscribe to this protest.—I remain, Sirs, yours faithfully,

J. PERCIVAL HUNT, M.D., F.R.C.S.P.,
Barrister of Lincoln's-inn, Lond., Surg. Army Med. Staff, and a subscriber and contributor to THE LANCET for over 22 years.

SOUTH LONDON AND THE HOSPITAL SUNDAY FUND.

To the Editors of THE LANCET.

SIRS,—The subject to which I endeavoured to direct attention in the letter referred to in your annotation under the above heading, was that, while valuable institutions like Guy's were languishing in South London for lack of funds, the effect of the present mode of distribution of the Hospital Sunday Fund is to transfer some £8000 out of £10,000 collected on this side of the river, to institutions situated principally at the West-end, where it might be supposed they were not so urgently required as in the poorer districts of the south and south-east. It is evidently no answer to this to quote the *dare quam accipere* motto, since the suggestion is not that those who contribute the money should receive it back, but rather that it should be spent in something like a fair proportion among the institutions which

Digitized by Google

minister to their needy neighbours. Nor, is it, I think, a valid reply, that the distribution is made in accordance with the fixed principles of the Fund, since that is a matter which has not been questioned. Nor, again, do I think it can be fairly said that it is too soon for Guy's, one of the "large and rich hospitals" you mention, to claim a share of the Hospital Sunday Fund. With 200 beds vacant for want of funds, with an income reduced from £40,000 to £25,000 through the agricultural depression, and yearly decreasing, obliged to appeal to the public for £100,000 in order to prevent a further reduction in the number of occupied beds, it seems to me that only ignorance of the facts can excuse (though it cannot justify) its further exclusion from the benefit of the Fund. I am happy, however, to agree with your concluding remark, that the matter should be brought before the annual meeting of the constituents, as well as before the Distribution Committee.

I am, Sirs, yours faithfully,

Dulwich, Aug. 6th, 1887. H. NELSON HARDY.

TRACHEOTOMY AND INFLATION IN THE TREATMENT OF A STILLBORN CHILD.

To the Editors of THE LANCET.

SIRS,—In answer to your correspondent, Mr. Watson, in the case of apparently stillborn children which occurs so very frequently in the ordinary routine of practice, I have met with very great success by adopting a course of procedure and treatment which, if efficacious, at the least is apparently a rather rough mode of restoring animation. The child being born and put into the receiver, I let the funis bleed a few drops; then rub the child's body all over with spirit—brandy or gin, whichever comes the handiest; a few drops, diluted, are put into the mouth; a hot sponge is applied to the heart and head, and likewise down the spine; and the mouth cleansed. I get the nurse to put her mouth in close contact with that of the child, and so make a direct and complete inflation in this way, keeping up a complete and direct means of artificial respiration. I have not much faith in any other form or means of artificial respiration. Of course in chafing the child with the spirit as it lies in the nurse's lap, a few little pats upon the buttocks will help to promote circulation. The above treatment failing, I place the child in a warm bath, but have never met from it any success, as the little patient has always then given up the tenancy of its short life.

I am, Sirs, yours, &c.,

Grosvenor Villas, Ramsgate, August 6th, 1887. CHARLES CHITTENDEN.

EDINBURGH.

(From our own Correspondent.)

UNIVERSITY COURT.

AT the last meeting of the University Court, the course of Practical Pathology, conducted by Dr. William Russell, was recognised as a qualifying class in the University Medical Curriculum.

GUESTS AT THE UNIVERSITY.

Last week the University extended its hospitality to the members of the Association of Mechanical Engineers, who held their annual gathering in Edinburgh this year, largely in consequence of the proximity of the Forth Bridge, which is now in an advanced stage of construction. The Association was formally welcomed to Scotland by the Marquis of Tweeddale, and to the University itself by Sir William Muir. During their visit the members inspected the Forth Bridge, and other important engineering undertakings in the vicinity of Edinburgh, and a series of social festivities were held in their honour. At one of these, a conversazione given by the Lord Provost of Edinburgh in the Museum of Science and Art, an address was delivered by Sir William Thomson on the subject of Ship Waves, which was attended by a large and interested audience.

THE UNIVERSITIES (SCOTLAND) BILL.

The draft of the Government Bill for the better administration and endowment of the Universities of Scotland has been published in the leading Scottish newspapers. It is considerably altered since it was drafted by a Liberal Government in 1884, and it is in some respects distinctly an improvement upon that measure. It is in all respects a happy circumstance that it is to be brought forward so near the end of the parliamentary session, and at a time when the corporate bodies whose interests are involved are in a state of summer relaxation and indifference. This constitutes its chief chance of passing into law, since it may escape the outburst of polemical contention by which its predecessors have been encountered and disabled; and, since there is nothing unequivocally bad in the text as now drafted, and a great deal that is good and much needed in Scotland, it is to be hoped that Mr. W. H. Smith's suggestion will be taken, and that the Bill may be allowed to pass without serious molestation. Another point in its favour is the scepticism with which its reality is generally regarded by those most interested in it. They are so accustomed to the appearance and disappearance of these forensic Will-o'-the-wisps that they will now scarcely take the trouble to follow the course of this most recent example of its class. The public press consider the Bill doomed, and properly so, by its containing clauses of a reactionary or anti-popular tendency. This view is not taken by those in academic circles, and unless some specific obstruction arises, it is probable that the bulk of the Scottish members will take this view, and favour the passing of the Bill in a but slightly modified form from that in which it now stands. There can be no doubt that a commission of intelligent and impartial men, such as that contemplated in the Bill, and with powers such as those proposed, cannot but greatly improve the efficiency of the Scottish universities as at present constituted, by effecting reforms vitally important to their continued prosperity.

DUBLIN.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS: HONORARY FELLOWSHIPS.

THE Council having recently conferred the Honorary Fellowship on several distinguished Surgeons, as mentioned in our last issue, a meeting of the College was held last week for the purpose. In opening the proceedings Mr. A. H. Corley, the President, said it had been his good fortune to occupy the presidential chair during the celebration of Her Majesty's Jubilee. It was consequently his privilege to be present in Westminster Abbey at one of the most impressive ceremonies of the century. He had personal gratification in taking part in that day's ceremony in being the instrument of conferring honour on distinguished merit. Their Honorary Fellowship was a diploma which they deemed beyond money and beyond price. It was only bestowed upon those whom they looked upon as among the foremost of their profession. It had been objected that, as similar institutions in the neighbouring kingdom did not reciprocate, they should be still more chary, but they could not help looking on this feeling as narrow and insular. In the City of Colles and Cheyne, of Carmichael and Graves, they could afford not to aspire to honours unless spontaneously bestowed, and they could afford to rise superior to those narrow prejudices which would debar them from conferring honour where honour was due. Sir George M'Leod and Mr. C. Macnamara, the only visitors who were able to be present, then signed the roll, and were admitted Honorary Fellows of the College. The new Fellows having returned thanks the proceedings terminated.

THE DUBLIN MEETING OF THE BRITISH MEDICAL ASSOCIATION.

The past week has been a busy one in Dublin, and it is gratifying to find that the meeting was in every respect successful. Independently of the scientific meetings which included some excellent contributions in medicine and surgery, the members, so far as the social part of the programme was concerned, had their hands pretty full. On Tuesday, at four o'clock, a special choral service was held at St. Patrick's Cathedral, where the Lord Bishop of Meath preached a most eloquent sermon. A service was also held earlier in the day in the Roman Catholic pro-Cathedral. The soirée given by the President (Dr. Banks) and the members of the Dublin Branch at the Royal University on Wednesday evening was very successful, and the decorations of the ball-room, which were carried out under the personal superintendence of Sir William Stokes, reflected the utmost credit upon that gentleman's good taste

Digitized by Google

On Thursday morning, in the new Leinster Hall, a breakfast was given by the Dublin temperance societies, and upwards of 300 sat down to a well-served repast. The same evening the public dinner took place, over 400 being present, and was honoured by the presence of his Excellency the Lord-Lieutenant. On Friday there was a garden party in the Fellows' Garden, Trinity College, which was well attended and very successful; an excursion to Christ Church Cathedral, when some interesting antiquarian details were given by the architect; and in the evening a conversazione, given by Surgeon-General Hassard, C.B., and the officers of the Medical Staff, in the Science and Art Museum. There was also a breakfast given to several members of the Association at the gardens of the Royal Zoological Society of Ireland, and every member present at the meeting had, if desired, his photograph taken and copies presented free of charge by an enterprising photographer. Dublin is noted for the hospitality of its citizens, and on this occasion it did not forfeit its usual reputation in this respect. Dr. Banks gave a banquet to leading members of the Association, at which the Lord-Lieutenant was a guest, and Sir George Porter followed closely in the good example set by entertaining several distinguished guests. I could mention many others who entertained their visitors in the most hospitable manner if it were at all necessary. Professor Rawdon Macnamara was unable to take any share in looking after our recent visitors owing, I regret to state, to severe illness, from the effects of which he is but now convalescing. The weather, it may be added, was all that could be desired, and the excursions which took place on Saturday were much appreciated by those who joined in them.

ROYAL UNIVERSITY OF IRELAND.

The Senate recently fixed the annual meeting of convocation for Friday, October 7th. The regulation permitting candidates to enter three times for the same examination on payment of a single fee has been repealed. The Senate have resolved to elect a curator, to take charge of all the University collections, instruments, &c., and be competent to act as examiner in one or more of the experimental or natural sciences.

MEDICAL HONOURS.

A London illustrated paper in its issue of the 6th inst. has given a portrait, and an excellent likeness it is, of a distinguished Dublin physician, and has stated that a baronetcy has been conferred upon him. I trust the announcement may be correct, for there is no member of the profession who will grudge Dr. Banks this mark of Her Majesty's approval; but at the time of writing this we in Dublin have had no official announcement of the fact. Several knighthoods have been gazetted, but the Jubilee Honours to medical men in Ireland have so far been conspicuous by their absence.

PARIS.

(From a Correspondent.)

FRENCH ASYLUMS.

THE Minister of the Interior has sent a circular to the Prefects calling attention to the fact that they are entrusted with the duty of periodically visiting public and private asylums, and explaining the great importance attaching to the discharge of this legal formality. The Minister enjoins one visit a quarter, and this to be made without the previous knowledge of the proprietor or superintendent of the establishment. The condition of the patients is to be ascertained, and all complaints heard; shower baths are to be abstained from as a mode of punishment; and a report is to be furnished after each visit of the general management of the asylum, detailing the care bestowed upon the patients, and the result of any inquiries which the visiting Prefect has thought it his duty to make with reference to any particular inmate. The removal of patients from one hospital to another before being definitely placed in a special asylum, a course of procedure which has been practised in certain departments, is strictly forbidden. The issue of this plainly worded circular is a step in the right direction, and the Minister of the Interior is deserving of all praise and assistance in his efforts, by no means too speedily taken, to do away with abuses in the control of lunatics in France.

HYGIENE IN FRENCH SCHOOLS.

The Academy of Medicine has to-day been occupied in the discussion of the conclusions come to by a committee appointed to report on intellectual overwork in schools and other places of education. After considerable discussion, in which MM. Lagenan, Trélat, Hardy, and Brouardel joined, the following conclusions were adopted:—"The Academy of Medicine calls the attention of the public authorities to the necessity of modifying, in conformity with the laws of hygiene and the necessities of the physical development of children and young people, the present arrangements of our scholastic establishments. It thinks that the colleges and lycées for boarders should be removed to the country; that wide, open spaces should be set apart for games; and that the class-rooms should be improved as regards lighting and ventilation." Without dealing with the course of study—which it desires to see simplified,—the Academy calls special attention to the following points:—Increase of the time for sleep as regards young children; for all pupils a diminution of the time devoted to study and classes—that is to say, to sedentary occupations—and a proportional increase of the time for amusement and exercise; the absolute necessity of submitting all the pupils to daily exercise in physical training proportioned to their age—namely, walking, running, jumping, formations, evolutions, regulated and prescribed movements, gymnastics with apparatus, fencing of every kind, games of strength, &c.

Paris, Aug. 9th.

Medical News.

VICTORIA UNIVERSITY: FACULTY OF MEDICINE.—The following gentlemen have passed the Final Examination:—

PART 1.—First Division: J. H. Barker, Owens College; F. E. Mathews, Owens College. Second Division: E. C. Lomas, Owens College.

PART 2.—F. C. Bury,* Owens College; F. G. Robinson, Owens College.

* Recommended for distinction in Medicine, Clinical Surgery, and Morbid Anatomy.

UNIVERSITY OF EDINBURGH.—At the graduation ceremony last week, the degree of Doctor of Medicine was conferred on the following gentlemen:—

‡J. Archibald, Scotland; *G. Armstrong Atkinson, England; ‡Thomas Ridley Bailey, England; Peter Bailie, Scotland; †G. Beckett Batten, India; J. Bowes, Scotland; ‡C. Boyce, Ireland; ‡R. Adams Brewis, England; *Alexander Bruce, Scotland; †J. Milne Chapman, Scotland; W. Jones Douie, Scotland; ‡Thomas Easton, Scotland; ‡Alexander Duncan Fraser, Scotland; C. Herbert Gage Brown, England; *J. Gibson, Orkney; W. Bruce Gowans, Scotland; †David Grant, Scotland; ‡Hugo M'Cauley Hardcastle, Egypt; James Heath, Ireland; ‡R. Dundas Helm, Scotland; Alexander Hewston, New Brunswick; J. Gilpin Houseman, England; †J. Hunter, Scotland; G. Irvine, Scotland; G. H. Kenyon, England; E. Dormer Kirby, England; David Laing, Scotland; ‡R. Laurie, England; C. Lewis Lightfoot, England; Duncan Romaine M'Arthur, Ceylon; Alexander Flyter Mackenzie, Scotland; R. Mackenzie, Scotland; ‡R. Mackinlay, Scotland; C. J. Russell M'Lean, Scotland; ‡Herbert Christopher Male, England; ‡J. Williamson Martin, Scotland; *W. Cornfoot Strettell Miller, Scotland; Daniel Mowat, Scotland; ‡J. Oliver, Scotland; ‡Donald Rose Paterson, Scotland; *R. W. Philip, Scotland; Adam Scott Purves, Scotland; ‡Daniel Ritchie, Scotland; ‡Ernest Roberton, New Zealand; †J. Robertson, England; Thomas Murray Robertson, India; ‡Frank Rothera, England; ‡Harry Scott, England; Joseph Stapleton, Australia; *John Stevens, Scotland; †Alex. Williamson Stirling, Scotland; †Henry Welch, England; ‡David Welsh, Scotland; ‡Claude Wilson, England; †Ralph W. Wilson, England.

* Those who have obtained Gold Medals for their Dissertations.

† Deemed worthy of competing for the Dissertation Gold Medals.

‡ Commended for their Dissertations.

The following candidates have passed the Final Professional Examination for the degrees of Bachelor of Medicine and Master of Surgery:—

Johnston Hamilton Acheson, England; C. M'Arthur Allan, Scotland; W. Allan, New Zealand; Douglas Hamilton Anderson, England; Jean Joseph André, Mauritius; Edmund Antrobus, England; Mihangel Ap Iwan, Wales; H. J. Bailey, England; John Barclay, Scotland; Herbert Llewellyn Barker, New South Wales; Benjamin Barnard, Mauritius; H. T. Barton, England; Gilbert Taylor Beatton, Shetland; C. H. Bedford, England; Albert Jobson Beebag, New South Wales; John Stothart Bell, Scotland; W. Leonard Bell, Scotland; W. J. Bell, England; Arthur Bentham, England; Wilfred W. Ogilvie Beveridge, Scotland; *Arthur Birt, England; Theodore Meyer Blumenreich, Scotland; G. Pirrie Boddie, Scotland; Douglas J. Mayhew Bone, England; H. E. Bower, England; C. W. Brown, Scotland; Daniel Walter Brown, England; James Brown, England; *Andrew Arthman Bruère, West Indies; Francis Oke Buckland, England; Ernest J. Burnett, England; Matthew Bernard Burton, England; T. W. Butcher, England; Francis John Butt, England; James Cameron, England; Walter Stuart Campbell, Scotland; W. Graham Campbell, Scotland; Ernest Christison Carter, England; G. Arnold Casalis,

* With distinction.

UNIVERSITY OF ABERDEEN.—During the past year the following candidates received the degrees specified:—

DEGREE OF M.D.—Lewis Daniel Alexander, Kilcreggan, Greenock; Joseph Carbery, Matale, Ceylon; Walter Smith Cheyne, Aberdeen; Alex. Gordon Davidson, Wartle; Matthew Dickson, Liverpool; Robert Hume Falkin, Clifton; T. Fiddes, Urmston, Manchester; J. Gerard, Aberdeen; David Hardie, Brisbane, Queensland; Patrick Letters, Dundee; Irvine Kempt Reid, King's Lynn; Ernest Barret Smith, Twickenham; James Taylor, Keith; Andrew Whyte, Brecon, Wales; J. Kennedy Will, London; James Wilson, Croydon, Surrey; J. T. Windle, Ovenden, Yorkshire.

DEGREES OF M.B. AND C.M.—W. Alexander, Fyvie; Alex. de Wet Allan, Aberdeen; C. Augus, Rhynie; Walter H. Atherstone, Cape Colony; Alex. T. G. Beveridge, Aberdeen; Fredk. Booth, Preston, Lancashire; J. Harley Brooks, London; Alfred Tennyson Brown, Banchory; James Bryce, Aberdeen; †J. Souter Butter, Letham, Forfar; James Orevie, Newburgh, Aberdeen; W. Christie Crowe, Aberdeen; J. J. Young Dalgarno, Peterculter; *David Macdonald Davidson, Mauritius; G. Davidson, Logie-Coldstone; T. Finlayson Dewar, Arbroath; C. Edmund Duff, Turriff; G. Hubert Ede, Wonersh, near Guildford; W. Boucher Evans, Maidstone, Kent; †A. Cornwall Ferguson, Aberdeen; Arthur Daniell Forbes, London; James Winton Fraser, Arbroath; T. Henderson Fyfe, Aberdeen; D'Arcy Harvey, Portland, Dorset; J. Duncan Hendry, Woodside, Aberdeen; G. Henry, Aberdeen; J. Eatough Holden, Bolton, Lancashire; †J. Johnstone, Port Chalmers, New Zealand; G. Alex. Kelman, Fearn, Ross-shire; †G. W. England Kerr, Bunchrew, Inverness; W. Leith, Turriff; G. R. D. Macdonald, Aberdeen; A. D. Mackinnon, Kilbride, Broadford, Skye; J. T. Macphail, Woodside, Aberdeen; Farquhar M'Rae, Tain; Guy Seymour Leslie S. Manning, Christchurch, New Zealand; J. Melvin, Aberdeen; R. Morrison, New Deer; J. Coutts Myles, Aberdeen; Patrick J. Smith Nicoll, Aberdeen; R. Henderson Nicolson, Aberdeen; J. Pearson, Sheffield; James Pirie, Elgin; Robert Rennie, Glenbuchat; D. Ross, Aberdeen; †Jonathan Shand, Keith; W. Booth Skinner, Torland; B. Smith, Aberdeen; C. H. J. Souter, Emmaville, N.S.W.; J. Souter, Aberdeen; †W. St. Clair Symmers, South Carolina; †T. Hector Thompson, Stonehaven; C. T. Dyer Urquhart, Aberdeen; J. Skirrah Abernethy Walker, Banff; Fredk. W. Walker, Darlington; G. Watt, Aberdeen; James Webster, Aberdeen; Creswell J. White, Chippenham, Wilts; and George Nicol Wilson.

* Highest academical honours. † Honourable distinction.

DIPLOMA IN PUBLIC HEALTH.—James Johnstone, Port Chalmers, New Zealand (with credit); G. W. England Kerr, Bunchrew, Inverness (with credit); George Watt, Aberdeen.

The following candidates have passed all the Examinations for, but do not receive the diploma in Public Health until they graduate:—

Alexander Ford Mackenzie, Alfred Morrison Saunders.

The John Murray Medal and Scholarship to the best graduate of the year was conferred on

David Macdonald Davidson.

The Thompson Fellowship was awarded to

James Johnstone.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the July sittings of the Examiners, held in Glasgow, the following candidates, having passed the respective examinations, obtained the triple qualification:—

Arthur W. Sandford, Edinburgh; W. B. Fellowes, Nottingham; Percy St. Johnstone, Birmingham; Douglas Wardleworth, Bury; Garibaldi Watson, Glasgow; Andrew C. Hunter, Paisley; J. C. Deuchar, Glasgow; James Mason, Glasgow; T. A. Davidson, Belfast; Alex. D. M'Lean, Partick; J. M. Ormond, Natal, South Africa; Manoel G. Pereira, Glasgow; David W. Scott, Glasgow; T. C. Jones, Corwen; J. Kennedy, Glasgow; David Lees, Glasgow; David L. Hamilton, Milford, Armagh; Alex. W. Pithie, Greenock Infirmary; Alfred E. Lackner, Edinburgh; J. Dunn, Ballykelly, Londonderry; Fredk. E. Welby, Edinburgh; J. Oldershaw, Liverpool; Jerome E. Vassaly, Scarborough; Richard H. Ward, Bromsgrove; Joseph Kelman, Airdrie; and W. R. Jones, Belfast.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the July sittings of the Examiners, the following candidates were admitted Licentiates:—

J. E. J. Deane, Rhymney, Monmouthshire; Alfred W. Statter, Wakefield; Fred. W. Burnett, Leeds.

The following were admitted Licantiates in Dental Surgery:—

W. Thompson Madin, Birmingham; John G. Wallis, Hull.

ROYAL UNIVERSITY OF IRELAND.—At the Summer Examinations the following obtained the Diploma in Sanitary Science of the University:—

Lawrence Corban, Henry A. Cummins, and Charles Fredk. Knight.

AT the recent annual meeting of the Falkirk Association for providing Trained Nurses for the Sick Poor it was resolved to establish a cottage hospital in the town.

A MASSAGE INSTITUTE FOR VIENNA. — Vienna is about to possess a great Massage Institute under the direction of Dr. Mezger. The general arrangements will be under the control of Herr Schüff.

SANITARY INSTITUTE OF GREAT BRITAIN. — The autumn congress of this Institute will be held in the town of Bolton on September 20th and following days, under the Presidentship of the Rt. Hon. Lord Basing.

IN a supplementary estimate in connexion with the Civil Service and Revenue departments, issued on the 5th inst., a sum of £2000 is put down as a grant in aid of the expenses of the Victoria University.

AT the last meeting of the Berlin Medical Society, Professor Virchow announced that Dom De Costa Alvaredo, a Portuguese physician, had, to show the esteem in which he held German medical science, bequeathed a sum of about £3000 to the Society.

DR. GIBSON, J.P., died suddenly of heart disease on the 8th inst. at Orton, Westmoreland. The deceased had published several local works, his last, "Legends and Historical Notes on North Westmoreland," having had a large circulation.

ON the 6th inst., on the occasion of the dedication at Barkingside of eighteen new cottages and of "Gairna House" to the cause in which he is engaged—viz., work among orphan and destitute children—Mr. Barnardo appealed for a hospital for his village. The cost of the proposed building is estimated at £3500, and of this sum £2000 has already been subscribed.

THE SCOTTISH UNIVERSITIES.—A Bill has been introduced into the House of Commons by the Lord-Advocate, the object of which is to make provision "for the better administration and endowment of the Universities of St Andrews, Glasgow, Aberdeen, and Edinburgh, and for the improvement and regulation of the course of study therein.

SAVING LIFE AT SEA.—The Select Committee of the House of Commons appointed to inquire into the efficiency of the present methods adopted to save life at sea are of opinion that the provisions of the existing Acts are inadequate and not suited to the requirements of the modern mercantile marine, and that these Acts ought now to be amended.

CAVENDISH COLLEGE, CAMBRIDGE.—The following statement has been sent to us for publication:—"It is proposed to form a new Association to take over and work this College, of which the special object is to enable young men to graduate at the University at an age earlier than is customary at other colleges, and to do so at as little expense as possible. Students can enter the College at sixteen and obtain the B.A. degree before they are twenty years of age. The unfinished state of the buildings, together with other circumstances, have hitherto hindered the success of the College, but an offer of £10,000 has now been made for the completion of the building provided means be found to place the College in other respects on a satisfactory footing. To do this £10,000 more is wanted, and for this sum an appeal is now made to the friends of education throughout the country. The claim of the College to support is based on the advantages which it offers to the very large class who desire a University education but cannot long defer the time when they will be earning their own livelihood. At a meeting of Cambridge residents held in Trinity College, the Master presiding, the desirability of forming the new Association under the no-profit clause of the Companies Act, 1867, so that it will be able to receive benefactions, was affirmed; and a committee, of which Mr. J. H. Flather, bursar of Cavendish College, is secretary, was formed to obtain subscriptions. It is believed that the County College Association is willing to make arrangements for the transfer of the College to the new Association, and it is very desirable to get this done, if possible, before the beginning of the Michaelmas term, so that the appeal is an urgent one."

MEDICAL NOTES IN PARLIAMENT.

Margarine (Fraudulent Sale) Bill.

In the House of Lords this Bill was on the 9th inst. read a third time. On the question that the Bill do pass, Lord Denman moved that "margarine" be changed to "rine" in the title of the Bill, and Lords Camperdown, Wemyss, and Rosebery supported the amendment, Lords Forteacue and Fitzgerald opposing it. On a division the amendment was rejected by 29 to 9.—Lord Wemyss, in moving the omission of Clause 7, which gave a power of inspection of margarine manufactories to police officers, stated that such power was without precedent in the case of ordinary manufactures, and would be a bar to improvements in process and machinery. The amendment was agreed to, and the Bill was then passed.

Hospitals for Women in India.

In the House of Commons on the 4th inst., in reply to Sir J. Lubbock, Sir J. Gorst stated that the reasons given by the Government of India for limiting to five years the appointment of a female medical officer to the Cama Hospital at Bombay were:—(1) The possibility of hereafter providing for the maintenance of the Cama Hospital on the grant-in-aid system; (2) the fact that the medical education of women in India is yet only in its infancy. The Secretary of State knew no reason why there should be any difference in the conditions of service of male and female medical officers, and he would commend an equality of treatment to the consideration of the Government of India. The Secretary of State has not heard of the suspension of any benefactions for the erection of hospitals for women in India from doubt as to the continuance of the employment of medical women by the Government in India.

Medical Officers in India.

On the 8th inst., in answer to Sir G. Balfour, Mr. Brodrick said that if reference were made to the Estimates for the present year it would be seen that the numbers and ranks of the medical officers on the Indian establishment who belong to the British Medical Staff are shown. A return could be given, if moved for, of the number of medical officers serving in India, in the colonies, and at home for any particular year. The Army Estimates did not purport to show the effective charge for any person serving in India, and it would be contrary to the whole principle on which the Estimates are prepared to include a charge for the medical officers in India.

The Vaccination Acts.

In reply to Mr. Pickersgill, Mr. Ritchie said that the penalties under the Vaccination Acts imposed in a metropolitan police-court are payable to the Receiver of Police under Sec. 47 of the Act 2 and 3 Vic., cap. 71, the statute under which the metropolitan police-courts were established. The sums so received by the Receiver are paid by him into the Exchequer. The law officers three or four years ago, when consulted on the subject, advised that whereas in these cases the penalties imposed were to go to the Crown or to such an officer as the Receiver of Police, the Crown was entitled, in the public interest, to apply for the enforcement of the penalty.

The Condition of the Thames.

On the 9th inst., in reply to Mr. Bigwood, Mr. Ritchie said that he had not received any complaints this year as to the state of the river Thames between Teddington and Isleworth. He had been furnished with a report from the assistant engineer to the Thames Conservators, who states that the expression "deplorable condition" cannot apply to the reaches between Teddington and Richmond, which have been recently improved by the Conservators, and is a very exaggerated description of the reach from Richmond to Isleworth. The assistant engineer to the Conservators, Mr. Ritchie added, says that the works which have been carried out by them have removed the whole of the shoals on the Surrey side between Teddington Lock and Richmond Bridge, and on the Middlesex side between the Lock and Orleans House, that dredgers and a large staff of men are at work continuing the improvements downwards, and that the section of river below Richmond Bridge will be taken in hand immediately. The expenditure incurred on these works up to June 30th last is stated to be £15,950, in addition to £21,000 previously expended upon the improvement of the navigation channel.

Lunacy Districts (Scotland) Bill.

On the 10th inst. the Lord Advocate moved the second reading of this Bill, stating that its object was to restore a power which existed before the Act of 1877, by which lunacy districts could be properly adjusted.—Mr. E. Robertson moved the rejection of the Bill, and the debate was continued by Sir G. Balfour, Mr. M'Ewan, Mr. G. S. Will, and others. Eventually the Bill was read a second time.

Births, Marriages, and Deaths.

BIRTHS.

BADDELEY.—On the 30th ult., at Newport, Salop, the wife of C. E. Baddeley, M.B.Lond., of a son.

BRISBANE.—On the 6th inst., at Park-road, Regent's-park, N.W., the wife of J. Brisbane, M.D., of a son.

CARTER.—On the 4th inst., at Putney-hill, S.W., the wife of Frederick H. Carter, F.R.C.S.Eng., of a daughter.

MAPLESON.—On the 6th inst., at Nottingham-place, W., the wife of Horsley Mapleson, M.R.C.S., L.S.A., of a son.

PEDLEY.—On the 6th inst., at Idmiston-road, West Norwood, the wife of M. Denison Pedley, F.R.C.S.Ed., L.D.S.Eng., of a daughter.

RICHMOND.—On the 3rd inst., at Greenhithe, Kent, the wife of Sylvester Richmond, M.D., of a son.

RUSSELL.—On the 27th ult., at Skipton-in-Craven, Yorks, the wife of William Russell, M.B., &c., of a son.

SUTTON.—On the 3rd inst., at Whitehall, Pontesbury, Salop, the wife of Alfred Martin Sutton, M.B.Lond., M.R.C.S., of a son.

UPTON.—On the 8th inst., at Rio Lodge, Brighton, the wife of Alfred Upton, L.R.C.P.Lond., M.R.C.S., L.S.A., of a son.

VINCENT.—On the 4th inst., at Beech House, East Dereham, Norfolk, the wife of Henry Bird Vincent, M.R.C.S., of twin sons.

MARRIAGES.

ARMITAGE—PLAYNE.—On the 9th inst., at St. Luke's, Moldenhead, Walter Stanley Armitage, M.R.C.S., L.R.C.P. Ed., to Ellen Armitage, third daughter of Alfred Playne, M.B., of Maidenhead.

CHÈVES—BRUCE.—On the 2nd inst., at Holy Trinity Church, Brompton, James Trelawny Chèves, M.R.C.S., L.S.A., to Bella, eldest daughter of Alexander Bruce, Q.C., of Hamilton, Canada.

HODGSON—IRDALE.—On the 9th inst., at St. Paul's Church, Carlisle, by the Hon. and Rev. the Earl of Mulgrave, assisted by the Rev. W. E. Strickland, M.A., Vicar, George Goodfellow Hodgson, M.R.C.S., of Bootle, Liverpool, to Josephine, youngest daughter of the late Joseph Iredale, Esq., of Portland-square, Carlisle.

MASON—JOHNSON.—On the 3rd inst., at the Parish Church, Knighton, Leicestershire, by the Rev. Edmund J. F. Johnson, M.A., Vicar of Elmore, Gloucestershire, brother of the bride, Hugh Herbert Mason, M.R.C.S., of Abbey Lodge, Barking, Essex, youngest son of the late William Mason, M.R.C.S., of Burton-on-Trent, to Susanna Louisa Roberts, second daughter of the late Edmund Johnson, of The Firs, Knighton.

MASON—WILKINSON.—On the 4th inst., at St. Pancras Parish Church, J. Wallis Barron Mason, M.D., to Mary Jane, elder daughter of the late Chas. Wilkinson, of Watford.

MAUGHAN—BECKETT.—On the 6th inst., at Great George-street Chapel, James Maughan, M.D., to Annie, eldest daughter of George Beckett, Esq., of Liverpool.

PETTIFER—KEELAN.—On the 3rd inst., at St. Paul's Church, Avenue-road, S.W., by the Rev. Cornish, Edmund C. Pettifer, M.B.Lond., of The Limes, Tillingham, Essex, to Minnie, youngest daughter of the late Henry Keelan, Esq., of Erin House, Dehra Doon, Deputy Superintendent, Great Trigonometrical Survey of India.

DEATHS.

HUTCHINSON.—On the 4th inst., at Woburn-place, Russell-square, W.C., Francis Hutchinson, M.D., aged 82.

MACDOUGALL.—On the 1st inst., at Kilblain House, Chesterfield, Aymer R. MacDougall, M.B., M.R.C.S.E., aged 39.

MURRAY.—On the 7th inst., at Great Cumberland-place, W., Gustavus Charles Philip Murray, M.D.

VAUGHAN.—On the 5th inst., James Vaughan, Deputy Inspector-General, R.N., of Alfred-place, Thurloe-square, S.W., aged 73.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM GENERAL HOSPITAL.—House Governor. Salary £300 a year, with board and apartments.

BRADFORD INFIRMARY.—Junior House-Surgeon. Salary £100 per annum, with board, residence, and washing.

BRISTOL ROYAL INFIRMARY.—Assistant Resident Medical Officer and Pathologist. Salary £80 per annum, with separate apartments, board, and laundry.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Assistant Physician.

DENBIGHSHIRE INFIRMARY, Denbigh.—House-Surgeon. Salary to commence at £85 per annum, with board, residence, and washing in the house.

FEMALE LOCK HOSPITAL, Harrow-road, W.—Assistant House-Surgeon. Board and lodging, but no salary.

LEEDS GENERAL INFIRMARY.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing.

LIVERPOOL DISPENSARIES.—Assistant Surgeon. Salary £80 per annum, with apartments, board, and attendance.

MANCHESTER ROYAL INFIRMARY.—Resident Surgical Officer. Salary £150 per annum, with board and residence.

PAROCHIAL BOARD OF PENNYGOWN AND TOBOSAY.—Medical Officer. Salary £100 a year.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Pathological Curator.

SUNDERLAND INFIRMARY.—House-Physician. Salary £80, rising £10 annually to £100, with board and residence.

WARRINGTON INFIRMARY AND DISPENSARY.—Senior Resident Surgeon Apothecary. Salary £100 per annum, with furnished residence and board.—Junior Resident Surgeon Apothecary. Salary £80 per annum, with furnished residence and board.

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—Resident Medical Officer. Salary £60 per annum.

METEOROLOGICAL READINGS.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE HUTTON FUND.

THE Secretary of the Hutton Committee begs the insertion of the final list of subscriptions. The amount collected has been invested in railway stock in the name of trustees for the benefit of Mrs. Hutton and her daughters, for whom it will form a permanent source of income.

Amount already acknowledged ...	£1067	12	6	Mrs. Swabey	£5	0	0
Sir Hugh Hume Campbell	25	0	0	Miss Lloyd	5	0	0
Mrs. Arundell Yeo ...	20	0	0	Dr. J. B. Fleming ...	3	3	0
Mrs. Wingfield... ...	20	0	0	Earl of Gainsborough...	2	2	0
Dr. Gibbons	5	5	0	Lady White	2	0	0
J. Astley Bloxam, Esq.	5	0	0	Dr. Whipham	1	1	0
					£1161	3	6

Dr. Hair.—Architects in designing churches are not guided so much by considerations of cubic space as by allowance for sittings, each seat usually being given thirty by twenty inches. To this must be added the space for passages. The total area, including passages and chancel, is for each sitting from nine to ten square feet.

Mr. W. W. Thompson.—We do not know which article is referred to. Any way, it is better to be guided by the advice of a qualified medical practitioner in the matter.

Mr. J. H. Sykes.—We must decline to answer the question.

ARSENIC EATING IN STYRIA.

To the Editors of THE LANCET.

SIRS,—As some doubt has been thrown upon this point, while the practice is otherwise fraught with considerations of a therapeutical or medico-legal interest, I venture to send you an authentic local pronouncement on the same, and to intimate that this was procured for me by a friend who had to visit her relatives in that country on her way with her husband to Bombay. Writing from Cuddalore, in the Madras Presidency, under the date of July 9th last, she says: "Herewith the information you asked for about arsenic eating; and as it was given me by my cousin, who is one of the doctors of the Lunatic Asylum at Gratz, you may rely upon it." I subjoin this gentleman's statement:—"The arsenic is taken by the Caryuthian and Styrian mountaineers principally. They take it with the view of getting good wind to enable them to climb their hills. They eat from half a grain to a grain a day, and begin with very small doses. When they wish to stop they are obliged to do so very gradually, for when suddenly stopped symptoms of arsenical poisoning set in. It does not appear to have any injurious effect on them; but when they get ill this drug has to be given to them along with the other medicines that are prescribed for them at the same time."

I am, Sirs, your obedient servant,

St. Leonards-on-Sea, Aug. 4th, 1887. W. CURRAN.

"DR. O. UPLAVICI" AND DYSENTERY.

WITH reference to our annotation of July 23rd on the Amœbæ of Dysenteric Stools a somewhat important verbal mistake occurred, which originated in and went the round of several German journals. These "erudite centralblätter" are now being subjected to some good humoured banter at the hands of the French journals for their ignorance of the fact that "O. Uplavici" is not an observer's name at all, but the Bohemian for "On Dysentery." All the credit which is given to the non-existent "Uplavici" really belongs to Prof. Hlava. It is only fair to say that the blunder having once been made it very naturally passed current, even a Russian journal making the same mistake. We have been unable to find any word at all like "uplavici" meaning dysentery either in Russian or Polish. The editor of the Russian journal in pointing out the mistake remarks that it ought everywhere to be corrected, lest the non-existent "Uplavici" should creep into treatises on medicine as an authority on dysentery!

Clean Wall.—If the walls were damp, the size would probably form a suitable medium for some bacteria, and unquestionably for mould fungi. If the walls were thoroughly dry, the organisms would not develop. But desiccation will not destroy spores; so that if we suppose that scarlet fever, for instance, is due to a microbe, we can quite understand how fresh outbreaks may arise from an infected room. We are of opinion that it is more healthy to discard wall-papers altogether in favour of distemper; but if wall-papers are employed, all the old papers should be removed and the walls well washed when repapering becomes necessary.

Enquirens.—We are unable to supply the information desired.

L. G. S.—The coroner is right.

CASE OF DISLOCATION OF THE FIRST PHALANX OF THE INDEX-FINGER, BACKWARDS.

To the Editors of THE LANCET.

SIRS,—I am urged by my principal, Mr. Sanderson, to bring this case to your notice on account of its rare occurrence in country practice.

R. J——, of Loftus, aged thirteen, on the morning of July 16th dislocated the index-finger of the right hand, backwards, by getting his hand caught in the leather band belonging to a revolving wheel at a ginger-beer manufactory. About half an hour after the accident the patient came into the surgery, saying he had put his finger out of joint. The finger was seen to be straight and immovable. The projection of the edges of the bones were very distinct, rendering diagnosis easy. Reduction was easily accomplished by holding the patient's hand in one's right hand, and placing one's right thumb upon the proximal end of the displaced phalanx, then grasping the index-finger with one's left hand and pulling the finger gently, and at the same time pressing the proximal end of the phalanx forward over the distal end of the first metacarpal bone. The bone slipped into position with a very audible click. The finger was then bandaged, and no swelling has resulted. The boy is now using his finger in his work as before, whilst he says that he has not felt any inconvenience at all from the accident. Mr. Sanderson informs me that although he has been in practice here over twenty years, he has never before had a dislocation of the index-finger, whereas he has had almost all other kinds of dislocations.

I am, Sirs, yours faithfully,
Loftus-in-Cleveland, July 27th, 1887. JAMES S. R. MILLER.

THE BROWN DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Please allow me to acknowledge the following contributions to the above fund.—I am, Sirs, yours faithfully,

G. STANLEY MURRAY, M.D.

20, Upper Richmond-road, Putney, Aug. 9th, 1887.

Amount previously received	£57	6	0	T. Taylor, Esq.	£0	10	0
Sir Wm. Jenner, Bart. ...	2	2	0	Dr. G. C. Dale	0	5	0
Sir Andrew Clark, Bart.	1	1	0	Dr. H. T. Sylvester ...	0	5	0
Dr. A. W. Orwin.. ...	1	1	0	R. B.	0	5	0
Dr. Granville Bantock ...	1	1	0	Anonymous	0	3	6
F. H. Gervis, Esq. ...	0	15	0	E. J. Parrott, Esq. ...	0	2	6

A. Goff.—Such questions as that mentioned by our correspondent are touched upon by us from time to time solely in the interests of public health. We cannot undertake to treat them from a merely social or economic point of view. To do so would be to travel beyond our province as medical journalists.

Dr. James Oliver's paper is marked for insertion.

CHARGES FOR WIVES AND CHILDREN IN CLUBS.

To the Editors of THE LANCET.

SIRS,—Would any gentleman inform me what is the usual amount paid per annum by members of clubs for medical attendance on their wives and children, midwifery not being included? The men themselves pay 4s. per annum.

I am, Sirs, yours truly,
Aug. 3rd, 1887. CLUB.

BENZOIN FOR ULCERATED LEGS.

Two Russian practitioners have recently pointed out the value of benzoin in the treatment of ulcers. Not, of course, that the virtues of this resin are at all unknown, as the existence and extensive use of friar's balsam during many centuries testify; benzoated lard, too, is frequently used as an application for ulcers. The strength of this is, however, very different from that of the ointments employed by the Russian writers. Dr. Voskresenski, a military surgeon, found that an ointment composed of two drachms of powdered benzoin with half an ounce of cerate and half an ounce of lard caused a number of ulcers on the limbs of soldiers of the 13th regiment, to which he was attached, to heal, some of them having existed for several years in spite of various other methods of treatment. Dr. Dorogoff, who practises in a country district where there are a number of Tartars and other Asiatics, whose nomadic and uncleanly habits are very favourable to the development of ulcers on the legs, writes in the *Ruskaya Meditsina* that, being unable to obtain indiarubber bandages for these people, he was very glad to try Dr. Voskresenski's plan, as it was cheap and simple. It proved a great success even in cases where nearly the whole of the lower limb was covered with ulcers. The preparation he employed differed in strength from Dr. Voskresenski's. Under its use the surface rapidly became covered with granulations, the induration left the edges, and the ulcers gradually cicatrised over, although he did not oblige the patients to lay up. He therefore strongly recommends this form of treatment as especially suitable for country practice where patients are obliged to work in the fields.

Mr. John J. Myers should apply at the office of the Crown Agents for the Colonies, Downing-street, W.

Rolyat will find the question treated in another column.

THE JURISDICTION AND PAYMENT OF CORONERS.

To the Editors of THE LANCET.

SIRS,—A Local Government Bill being imminent, and a reform of our coroners' courts no less so, it appears to me that the jurisdiction of a coroner should be made coterminous with a Parliamentary division or group of divisions. As a Parliamentary division is the basis for the scheme of local government, it would be an anomaly that coroners should continue to be appointed, so that their jurisdiction would extend into, and their payment be made by, various portions of various Parliamentary divisions. The same argument applies to the appointments of medical officers of health.

I am, Sirs, faithfully yours,
Thaxted, Essex, Aug. 4th, 1887. WM. SUNDERLAND, M.R.C.S., &c.

Intending Medical Emigrant had better perhaps refer his budget of questions to the editor of "India and the Colonies." We know of no source whence the whole of the information desired may be obtained.

Mr. G. Bishop.—Yes.

BALDNESS.

To the Editors of THE LANCET.

SIRS,—I observe you have an article on the above subject in the current number of THE LANCET. I consider the effect of hats in producing baldness cannot be over-estimated. They do so by obstructing the circulation of blood to and from the scalp. Were hereditary predisposition the main factor in the production of baldness, the affection would obviously be equally common in both sexes, which it certainly is not, but is especially prevalent in the male sex, whose hats obstruct the circulation, whilst those worn by the opposite sex do not.

I am, Sirs, yours faithfully,
Aug. 2nd, 1887. OBSERVER.

J. Y. (Glasgow).—Angelo Nannoni of Florence. No history of lithotomy can be complete without reference to the improvements effected in the operation by that great Tuscan practitioner. He was born at Incisa in 1715, and rapidly rose to be the head of the Tuscan school in surgery and surgical therapeutics. His cast of mind was essentially philosophical, and Italians have compared him to the late J. Henry Green among ourselves. His writings fill an honoured place in the medical libraries of the peninsula. He died July 30th, 1790.

Enquirens.—We must adhere to our rule.

THE MOXON MEMORIAL.

To the Editors of THE LANCET.

SIRS,—As it is highly desirable that the subscription list of the Moxon Memorial should be closed forthwith, and as several gentlemen who gave their support have not yet forwarded the sums promised, may I request through your columns that those who have not yet sent in their subscriptions should do so without further delay?

I am, Sirs, yours faithfully,
B. CLEMENT LUCAS, Hon. Treasurer.
18, Finsbury-square, E.C., Aug. 9th, 1887.

ERRATUM.—In the paragraph headed "Carbolate of mercury in syphilis," in our last issue, p. 277, the quantity of carbolate should have been stated as 1/2 grains, not 5 grains.

The Bradshawe Lecture

ON

PNEUMOTHORAX,

Delivered at the Royal College of Physicians, Aug. 18th, 1887.

BY SAMUEL WEST, M.D., F.R.C.P.,

ASSISTANT PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL; PHYSICIAN TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK; AND PHYSICIAN TO THE ROYAL FREE HOSPITAL.

MR. PRESIDENT,—By appointing me, Sir, to deliver this lecture, you have paid me an honour which I am proud to acknowledge; and although, for the moment, the feeling of honourable distinction is lost in one of responsibility, still the confidence which your judgment always inspires relieves some of the anxiety I feel lest my ability should not prove equal to the task you have imposed upon me.

I have chosen Pneumothorax as the subject of my lecture—a subject so large, however, that I cannot undertake to deal with the whole of it within the time placed at my disposal, and I intend to limit my remarks to those parts which present especial interest or which call for further elucidation.

Of the causes to which pneumothorax is due, phthisis is the chief. This is the primary lesion found in at least 90 per cent. of all cases. When from the remaining 10 per cent. are excluded those cases in which pneumothorax is the result of gangrene or acute inflammatory destruction of the lung, or the consequence of injury to the lung or walls of the thorax, the percentage of the other assigned causes becomes very small; 2 or 3 per cent., perhaps, will include them all. It would be unprofitable to spend time in considering most of these groups, and I wish to refer to only two: first, that in which pneumothorax has occurred in apparently healthy persons; and, secondly, that in which the pleural cavity has been laid open by injury.

Many cases have been recorded, especially in recent years, of pneumothorax in the apparently healthy; but, as in these recorded cases recovery seems always to have taken place, there has been no opportunity of proving or disproving conclusively the existence of a pulmonary lesion. The question is thus raised whether it is possible to rupture the healthy lung by any force which respiration can bring to bear upon it. To this question an affirmative answer must be given. The violent paroxysms of whooping-cough and the straining of parturition afford clinical evidence that the lung may be ruptured by expiratory efforts. The condition, however, which is commonly produced is not that of pneumothorax, but that of subcutaneous emphysema.

A careful experimental study of this subject has been made by Dr. Champneys upon the lungs of infants.[1] When the lung is over-distended and gives way, the air first makes its way beneath the pulmonary pleura, stripping it easily off for some distance from the surface of the lung. It then passes along the root of the lung to the mediastinum, and following thence the course of the cervical fascia it reaches the subcutaneous tissue of the neck, whence it may spread over the whole body. If the pleura give way, the place of rupture is to be found usually near the root of the lung; but although pneumothorax did now and then arise in this way, the usual result was that already described—namely, emphysema of the mediastinal tissue and of the neck. Sometimes by artificial respiration after tracheotomy the air has taken the reverse direction, and, tracking downwards from the tracheotomy incision along the deep cervical tissue, has reached the mediastinum, or even the subpleural tissue, and occasionally the pleura has been ruptured and pneumothorax produced.

These experimental observations are confirmed by clinical evidence. Dr. Champneys records twenty-seven necropsies[2] after tracheotomy. Mediastinal emphysema was found in [illegible] and in two of these pneumothorax was present. The pneumothorax in one of them was double, and the cause of death. In eighty-two necropsies[3] at the Children's Hospital mediastinal emphysema was found in five, but pneumothorax in none. Wilks and Moxon[4] mention two cases of pneumothorax after tracheotomy, and connect it with mediastinal emphysema. Dr. Angel Money,[5] examining twenty-eight similar cases with especial reference to this point, found mediastinal emphysema in no less than sixteen and pneumothorax in two, but in both of these the pneumothorax was associated with mediastinal emphysema. In most of these cases artificial respiration had been performed.

It seemed desirable, considering the delicate texture of the infantile lung, to repeat these observations upon the adult, and I did this, with the result of confirming in the main the conclusions at which Dr. Champneys had previously arrived. I noticed also in my experiments the same important and curious fact to which Dr. Champneys has referred—namely, the difficulty of obtaining bursting pressure by means of water, owing to the permeability of the lung to water while it is still air-tight. The lung seemed almost like a sponge, so that the water flowed from it with such readiness when distended that the pressure could not easily be maintained.

The pressures at which rupture took place varied much in different cases. In four cases it reached two and a half inches of mercury, in one two, and in another four; so that what Dr. Champneys found in infants is true also in adults—that the normal resistance of the lung is widely different in different persons. My own observations were made upon the lungs after removal from the body, and the bursting pressures thus obtained are no doubt much below those which would be required when the lungs are *in situ*. In the only case in which I was able to attempt this experiment upon the dead body, the air did not appear in the neck until a pressure of nearly eight inches of mercury was registered, and pneumothorax was subsequently found on both sides. This experiment agrees with the statement made by Hutchinson, that the cells of the lung can resist a pressure of from three to nine inches of mercury when expanded as in health.[6]

I append the actual notes made at the time of experiment, and I wish to acknowledge with thanks the assistance I have received from Mr. Willoughby in this work:—

1. Left lung; adult man about fifty. Septicæmia after osteo-myelitis of femur. Lower lobe good deal collapsed, especially on posterior and lower part; no consolidation, no old adhesions. Lung expanded readily in all parts, except where there was collapse. The pressure was raised to two and a half inches of mercury, and the lung then burst at the posterior and middle part of upper lobe, about two inches from root of lung. When rupture occurred the pleura was suddenly stripped off over a space about the size of a five-shilling piece, and then it gave way, the hole measuring about one-eighth of an inch. The tube was next tied into the bronchus of the lower lobe; as the pressure rose some of the collapsed portions expanded, but not all. The lung finally ruptured suddenly on the posterior border, where the lung lies at the side of the spinal column. Here the pleura was suddenly stripped off the lung for the whole length of the lobe (six inches), and this gave way with a rent about half an inch long. On opening the raised part of the pleura the lung was found to be ruptured in several places; for the most part the holes were minute, but in one, which corresponded with a small portion of collapse, the hole was nearly one-eighth of an inch in diameter.

2. Left lung; adult man about fifty. Lung good deal collapsed; small fibrous nodules felt through the pleura, scattered throughout the lung; an old fibroid cicatrix at the apex. The lung distended readily (even the collapsed portions), and resisted a pressure up to four inches of mercury. At this pressure it gave way in the posterior and middle portion of the upper lobe; the pleura stripped off for a space about the size of a shilling, and then burst by a small aperture. The tube was fixed in the lower lobe, and the pressure was now raised to nearly five inches of mercury before any considerable rupture occurred. This took place at the posterior border, close to the root of the lung, but the pleura did not strip off, as in the last case. Before this pressure was reached many small patches of interstitial emphysema developed all over the surface of the lobe, but none of them burst. On section a fibrous nodule was found in the apex, and small nodules (so-called "peri-bronchitis") scattered throughout both lobes.

Digitized by Google

3. Right lung of a boy. The cannula was tied in the bronchus and the lung inflated; at a pressure of two and a half inches of mercury it burst. The air came out of minute apertures around the inferior bronchial vein and along the posterior and mediastinal borders; some air seemed to come from the vein itself. The inferior lobe burst first, but there was a large slit accidentally made in the upper lobe before the experiments began. Where the lung burst, except close to the root, the pleura was first raised. It was not stripped off in large pieces, but in pieces varying from a large pea downwards in size.

4. Left lung of male, aged about fifty-five. Died after gastrostomy for stricture of œsophagus. Upper lobe particularly emphysematous, lower lobe not so much so; otherwise healthy. Air was forced into the lower lobe only as the upper one was cut. At a pressure of two inches of mercury the pleura was suddenly slightly raised in two or three places near the vein, and air came up also through the vessels. The holes were very minute in the lung-substance, and the pleura raised was about the size of a pea in each place.

5. Left lung of male, aged sixty-six, who died after cancer; stomach emphysematous, but otherwise healthy. At a pressure of two and a half inches of mercury the pleura was suddenly raised up over an oval space, longest diameter two inches, shortest three quarters of an inch. The part raised was the part covering the lower lobe where it was opposite the upper (that is, between the two lobes), and near the root.

6. Left lung of male, aged about fifty, who died suddenly from bursting of aneurysm of aorta, situated where thoracic becomes abdominal aorta. The aneurysm burst into the right pleura. Air was forced in, and at a pressure of two and a half inches a part of the pleura, one inch and a half long and one inch wide, was suddenly raised from the lower lobe close to the root. At the same time air came up through both artery and vein. The hole in the lung itself could not be seen; the hole in the pleura, which was raised, was a quarter of an inch in diameter.

A pressure of eight or nine inches of mercury is far beyond anything that even an adult can produce by expiratory effort; and it is clear, therefore, that it can only be in cases where the normal resistance of the lung is greatly reduced that in the absence of any disease of the lung pneumothorax can be produced. The lung is, therefore, capable of resisting in most cases the highest pressure that the most violent expiratory efforts can bring to bear upon it, and the question may well arise whether in those cases in which the lung has given way the absence of a local lesion can be without hesitation assumed. However this may be, it is clear that when rupture of the lung occurs, the result is usually subpleural, mediastinal, and cervical emphysema, and only very rarely pneumothorax. This conclusion clinical observation abundantly confirms. Although every text-book speaks of emphysema among the complications of whooping-cough, pneumothorax is by most writers not even mentioned, and so far as parturition is concerned, Dr. Matthews Duncan allows me to state that, although emphysema is by no means uncommon, he has never yet seen a single case of pneumothorax produced during parturition.

If now we turn to the cases recorded in which pneumothorax has occurred in the apparently healthy, it is remarkable that in so many there is a complete absence of any history of forcible respiratory effort. In some the pneumothorax developed actually during sleep; in others when the patient was sitting still or walking quietly. In a few it occurred during effort, but in many of them the efforts could not for a moment be compared in violence to those of parturition or whooping-cough. It is therefore probable that in these cases the lungs were not really sound. This conclusion raises another question of importance. If the lungs were not sound, is it not remarkable that recovery should so often occur? In the first place, it is well known that lesions may exist in the lung which no skill in physical diagnosis may be able to detect, and that such a lesion is capable of producing pneumothorax the following case provides proof:—

A man, aged fifty-six, was admitted into St. Bartholomew's Hospital with some shortness of breath; and, on examination, he was found to have pneumothorax of the right side. He gradually sank and died; and, on the post-mortem examination, the only lesion in the lung to be found was a small cavity with caseous walls, the size of a hazel-nut, near the root of the lung. This had ruptured into the pleural cavity.

But it might be objected that pneumothorax due to the rupture of a phthisical cavity would hardly recover. Such an assumption is not warranted by clinical experience.

Martha L——, aged nineteen, was admitted into the Chest Hospital, Victoria Park, with phthisis of the right apex. About a fortnight later pneumothorax was discovered on that side. She had had an indefinite attack of sickness, to which no importance had been attached, a few days before I saw her. The signs of pneumothorax were characteristic. No fluid developed, but after a few days the air began slowly to disappear, and in about nine weeks had completely vanished. The lung had re-expanded, and the breathing was audible as before over the whole side. While the pneumothorax on the right side was getting well the mischief in the opposite lung was rapidly advancing, and the patient was sinking of consumption. She was removed from the hospital against advice, and I heard that she died a few days later. The signs of pneumothorax had completely disappeared for more than a fortnight before her departure from the hospital. In such a case there can be no reasonable doubt of the phthisical nature of the lesion, and yet recovery was complete.

In another case in which complete recovery without effusion took place,[7] I have repeatedly examined the chest with great care, and have always failed hitherto to obtain any definite signs of local lesion. The patient has, however, had three or four attacks of slight hæmoptysis, and I think the probabilities are in favour of a phthisical lesion. It is now four or five years since the patient had pneumothorax, and he continues in his usual health.

From these facts, therefore, that lesions may exist in the lung, which cannot be detected, and that recovery from pneumothorax may be complete even when the lesion is presumably phthisical, supported as it is by the experimental and clinical evidence already brought forward, we are led to the conclusion that in many, if not all, of the cases occurring in the apparently healthy, a lesion, which may even be of a phthisical nature, has really been the cause of the affection.

I turn now to the second class of cases to which I wish to refer—namely, to that in which the pleural cavity has been laid open by injury. The mechanism of pneumothorax in these cases is thus described: "The elastic pulmonary tissue is always to a certain extent on the stretch. It is always, so to speak, striving to pull asunder the pulmonary from the parietal pleura; but this it cannot do, because the air can have no access to the pleural cavity. When, however, the chest ceases to be air-tight, and air is introduced into the pleural chamber, the elasticity of the lungs pulls the pulmonary away from the parietal pleura, and the lungs collapse."[8] This quotation expresses concisely the physiological doctrine of the day. It is not, however, completely correct, for the chest may cease to be air-tight, and yet air may not enter the pleural cavity. If, however, air does penetrate between the layers of the pleura, the lungs collapse, as they are stated to do, by virtue of their own elasticity. Experiment upon animals, as well as observation of disease and injury in man, establish the truth of this latter statement; but there are not a few instances in which, in spite of the pleura being opened, collapse of the lung does not occur, and air does not therefore enter the pleural chamber. In considering the whole question, these instances must not be disregarded. There are two great classes of such cases: first, that in which the pleural cavity has been laid open by an external wound; secondly, that in which, without any external wound, a communication between the lung or some other air-containing viscus and the pleura has been made by an internal lesion.

In the first class of cases, where the side of the chest may have been laid open by a tear or cut, the lungs are sometimes seen torn and bleeding in the floor of the wound, but still in close apposition to the walls of the thorax. A very striking case of this kind is recorded in the St. Bartholomew's Hospital Reports for 1876.[9] A wood-turner, aged thirty-three, stabbed himself in the head, chest, and abdomen with a chisel. The wounds of the head and abdomen were not very severe, but the wound in the chest, situated on the left side between the fifth and sixth ribs, was three inches long. Through it the lung could be easily seen wounded and bleeding. This wound in the chest was closed with strapping and oiled lint. Two days later there was emphysema, but

[7] Clin. Soc. Trans., vol. xvii., p. 56. [8] Michael Foster, Phys.
[9] Surgical Appendix to the Statistical Tables.

Digitized by Google

this soon cleared up, and in four weeks the patient recovered completely without any further trouble.

The second class of case, in which, without any external wound of the thorax, the lung is torn and the pleural cavity opened, is still more interesting, as it is also much more frequent. Simple fracture of the ribs is one of the commonest of surgical injuries. Pneumothorax, however, in these cases is extremely rare, and yet it is clear that both layers of the pleura are torn across and the lung opened, from the fact that air has made its way into the subcutaneous tissue, producing surgical emphysema. It is hardly necessary to bring forward proof of such a well-known fact, but it may be useful to quote one case in point, the most remarkable I have myself met with. I made the post-mortem examination upon the body of a woman who had been crushed by a waggon. There was no external wound beyond bruising, but several ribs were fractured, and a considerable amount of subcutaneous emphysema developed. The lungs had been severely injured, it was evident, for the patient had expectorated a good deal of blood. At the necropsy several ribs were found fractured, and the lung extensively torn over an irregular area about two inches in diameter; but in spite of this the lung was everywhere in apposition with the chest walls, and there was a complete absence of pneumothorax. The pleural cavity was free from adhesions. The case puzzled me much, and, having at the time no better explanation to offer, I assumed that the lungs must have become hitched over the protruding and jagged ends of the bones, and have been in this way prevented from collapsing.

Without bringing further evidence forward, I am expressing, I believe, only the common experience when I say that with simple fracture of the ribs pneumothorax is very rare, and surgical emphysema very common. This is a great difficulty, and various solutions have been proposed. It has been asserted that in such cases the pleural cavity has either been completely obliterated by previous disease, or that adhesions rapidly formed round the wound have sealed the pleural cavity. This theory is *a priori* improbable. It has no clinical facts to support it, and it is disproved by post-mortem examination. It is by others asserted that air does enter the pleura, but that it is rapidly absorbed again, so that its absence after death is accounted for. When so careful a clinical observer as the late Dr. Hilton Fagge[10] endorses this view, the need of reconsideration of the whole question is evident. These explanations are unsupported by clinical observation, and are one and all disproved by post-mortem examination. The fact, therefore, that the pleural cavity may be laid open, and yet that collapse of the lung with consequent pneumothorax may not occur, must be accepted, and an explanation sought.

The normal elasticity of the lung was calculated by Donders[11] to be equivalent to seven millimetres of mercury. Michael Foster rates it somewhat lower—namely, at five millimetres.[12] Hutchinson agreed with the higher estimate, as the result of direct determination upon the lungs of two criminals immediately after death. If for the present purpose the higher estimate be accepted, it follows that when the lung does not contract after the pleura is opened it must be kept on the stretch by some force greater than seven millimetres of mercury; and there seems to be no place for such a force to exist, unless it be in the pleura itself; and if here, it is probably to be found in the cohesion between the two serous surfaces. A theory of this kind seemed to admit of easy investigation, and it was put to the test in the following manner.[13] Two discs made of mahogany were taken. They measured two inches (five cubic centimetres) in diameter, were smooth on the surface, and had a groove cut round the margin. Over these, pieces of stomach were tightly stretched, with the peritoneal surfaces outwards, care being taken to select pieces which would lie as smooth and even as possible. These two discs so covered moved very freely over one another; but when they were pulled straight asunder, considerable force was required to separate them. In order to estimate this force, one of the discs was connected with the arm of a balance, and while the other was fixed fast weights were placed in the [illegible] until the two were pulled apart. I found in [illegible] my experiments that about [illegible] It was thought that the force

[illegible] Med., vol. i. p. 966.

[illegible] vol. v., p. 1058.
[illegible] in a paper communicated to the
[illegible]

which kept these discs together might have been atmospheric pressure, and in order to eliminate this two similar discs were taken, perforated in the centre by a hole a quarter of an inch in diameter. Corresponding with this hole in the lower disc, a cut half an inch long was made completely through the membrane. The retraction of the membrane converted this slit into an oval hole, and in this way, when the discs were placed in apposition, a free communication was provided between the air and the space between them. I found, however, that the same weight was still required—namely, 325 grammes—to separate them. A similar slit was made next in the upper disc and membrane as well, but this, too, made but a few grammes difference. The result of these observations is to prove that there is some force other than atmospheric pressure[14] by which these two smooth surfaces are held together, and, without using the term in too technical a sense, I may speak of it as cohesion.

The next point to be determined was this—Was this cohesion greater or less than the elasticity of the lungs? Accepting, for the sake of the calculation, the higher estimate made by Donders—namely, seven millimetres of mercury—it was found that a column of mercury of this height, with a circular base of five cubic centimetres in diameter, weighed 185·6 grammes.[15] The weight required to separate the discs was 325 grammes, so that there was an excess of about 140 grammes in favour of the force which kept the discs together. If this weight be reckoned out in terms of mercury, it is equivalent to 12·5 millimetres as opposed to seven millimetres, giving thus an excess of 5·5 millimetres.

Having thus roughly established the correctness of the theory, I endeavoured next so to modify the experiment as to imitate somewhat more closely the conditions which exist in nature. I took a bell-jar, the mouth of which was about three inches in diameter. The top was bored so as to provide for the insertion of a perforated cork, into which a glass tube could be fitted and communication made in this way between the external air and the interior of the jar. Over the mouth two pieces of stomach were stretched with the peritoneal surfaces in contact. By exhausting the air the membranes were made to bulge inwards; they remained, of course, in contact. A slit was now carefully cut through the outer membrane, forming an oval hole about half an inch long and a quarter of an inch wide. This hole provided for the access of air between the membranes, just as in the case of the discs. When the air was now exhausted, the two membranes still remained in contact as at first, and it was only after considerable bulging that they separated and air passed between them. A manometer was now connected with the interior of the jar, so that the pressure could be measured. By means of a special modification of the mercury manometer, the reading could be converted at once into its equivalent in inches of water.

7·0 millimetres of mercury = 3·8 inches of water.
12·5 " " = 6·8 " "

The jar was now exhausted until the negative pressure indicated was 3·8 inches of water. At this pressure, the equivalent of the elastic tension of the lung, the membranes remained in contact. The exhaustion was continued until a pressure of 6·8 inches of water was reached, but still the surfaces remained in contact. The pressure could even be slowly still further reduced to 10 or 12 inches of water before the surfaces separated and air passed between them. When the pressure was relieved they again passed into contact, often so completely that the original experiment could be repeated. More often, however, unless the membranes had been very carefully stretched, a few small bubbles of air remained, which had to be pressed out with the finger to make the contact perfect.

It is not to be wondered at that with the bell-jar experiments higher values were obtained for the force of cohesion than with the discs. It is clear that although I had discs of five centimetres in diameter covered with membrane the actual surface of contact was something less than this, and the results obtained were therefore below the real value. While this value was in all probability too low, I accepted for the purpose of comparison the highest estimate of the

[14] Cohesion between two smooth glass plates is independent of atmospheric pressure. (Draper's Medical Physics.)

[15] A disc of five centimetres in diameter has an area of $5^2 \times 0{\cdot}7854 = 19{\cdot}635$ square centimetres. Seven millimetres of mercury upon the square centimetre = 9·45 grammes. A pressure of seven millimetres of mercury upon a disc of five centimetres = $19{\cdot}635 \times 9{\cdot}45 = 185{\cdot}6$ grammes.

Digitized by Google

elasticity of the lungs, so that on both accounts the difference arrived at was less than the real difference.

With the bell-jar experiment certain precautions are necessary. The two pieces of membrane must be such as will stretch uniformly. This makes the parietal pleura itself not a very suitable membrane for experiment. It is much thinner in the parts corresponding with the ribs than it is in the parts corresponding with the intercostal spaces. The thinner parts yield most on exhaustion of the jar, so that the surface is thrown into furrows, and the tension on bulging differs in consequence in different parts. This affects greatly the results. The stomach is more suitable; but even with this, care must be taken in the selection of the parts used, for when stretched the large bloodvessels act as bands, and if they be included folds are also produced.

The membranes also must be so stretched as to have as nearly as possible the same tension in each. If this be done the surfaces may remain in contact at much greater negative pressures; it may even be at 2 inches of mercury before separation is effected. This result was so much in excess of what I anticipated that I sought for some explanation of it. While the membranes were on the stretch, therefore, at this pressure, I gently raised the edges of the slit with a blunt probe, so as to admit a little air between the membranes here, and I found then that the two layers separated at once. I repeated the experiment at different pressures. As the pressure was reduced more and more, the ease with which air passed between the layers when the edges were raised became less and less, until when the pressure was below 12·5 millimetres of mercury—that is, below the pressure at which the force of cohesion had been estimated,—in spite of the edges being freely separated by the probe, the membranes did not separate, but directly the outer layer which had been lifted up was allowed to fall, it passed again into close contact with the other, and the air which had been admitted was forced out. This experiment appears to me to be conclusive.

The figures given above are actual numbers obtained in particular experiments. The numbers differ a good deal in different observations, their variations depending upon differences in the stretching of the membranes, and in the condition of their surfaces at the time of experiment. Without laying, therefore, any special stress upon the actual values obtained, these observations establish, I consider, the existence of a force between the pleural surfaces much in excess of the elasticity of the lungs, and sufficient therefore to maintain the lungs in apposition with the walls of the thorax, even when air has free access to the pleural cavity.

Pneumothorax can, therefore, be no longer regarded as a condition to which there is an inherent tendency in the healthy body, but, on the contrary, as a condition brought about by the forcible separation of the pleural surfaces, and in this respect exactly analogous to the distension of the subcutaneous tissue, which occurs in surgical emphysema; and, considering the frequency of subcutaneous emphysema and the rarity of pneumothorax in simple fracture of the ribs, to which reference has been made, it would seem to follow as a corollary that the force required to distend the subcutaneous tissue must be less than that required to separate the layers of the pleura. Pneumothorax, therefore, so far from being, as it is commonly regarded, a passive process, and inspiratory in origin, is really expiratory in its initial stage, and requires an active force to produce it; and surgical emphysema, so far from implying, as Fagge asserts, the necessary antecedence of pneumothorax, may in reality be a protection against it, the air making its way in the direction of least resistance, beneath the skin rather than between the pleural surfaces. It is evident, further, that where the pleura is laid freely open, so that the air passes away without hindrance or expiration, the liability to pneumothorax will be still furthur reduced, for the expiratory pressure requisite to overcome the cohesion of the pleural surfaces will be absent.

By means of the discs I have been able to investigate some of the conditions which modify the force of this cohesion. In the first place, the surfaces must be absolutely smooth, for any roughness prevents close contact. This is one of the reasons why stomach well stretched over the discs is more suitable than pleura, the mucous membrane forming a cushion into which any little unevenness will sink. I have frequently found that the same pieces of pleura which would not give good results when spread directly on the discs answered admirably as soon as they were stretched with a piece of stomach beneath them.

The surfaces in contact must be neither dry nor wet, but simply moist, as are the normal surfaces of the pleura. If dry, they will not cohere at all; if wet, the force of cohesion is greatly reduced. The cohesion is, however, not between the membrane and the surface of the fluid, for a disc floated on water, blood, or serum requires but little force to raise it out. What is essential appears to be an extremely fine film of fluid, a capillary film, if I may call it so, between the two surfaces. It may be that the cohesion varies with the nature of the fluid; but, so far as I have gone at present, I do not find, with my rough methods of investigation, any perceptible difference between serum, blood, or water. The reason abolition of this cohesion by the presence of even a small excess of fluid is important, for there will be, on this account, less resistance to the entrance of fluid than of air into the pleura. This force of cohesion has a general bearing in physiology, for it will exist wherever serous surfaces are in close contact; in the peritoneum therefore, and in the pericardium as well as in the pleura. In the peritoneum its tendency will be to keep the intestines partly distended, and in this way it will diminish resistance to the passage of its contents along the tube. It will be, perhaps, in the joints that one of the most interesting illustrations of its usefulness will be found, for it is compatible with the freest movement possible of the surfaces upon each other. It may, perhaps, prove to be one of the most important means by which the head of the femur is kept in the acetabulum, but it will come also into play even in the hinge-joints. Since the force appears to be directly proportional to the extent of surface of contact, it will continue to be the same so long as the extent of surface of contact does not vary, and in the hinge-joints, therefore, so long as this is the case, the same amount of force will be exerted, whatever be the position of the joint, to keep the ends of the bones in place. The effect of excess of fluid in diminishing or even abolishing this force is well illustrated by the looseness which develops in the joints when effusion takes place into them.

But to return to the pleura, with which we are now more especially concerned. The existence of this force of cohesion is sufficient to explain satisfactorily many of the clinical difficulties which present themselves, and which led me to institute these investigations.

Among the physical signs of pneumothorax, the chief interest centres in the variations of pleural pressure and their consequences. If the observations to which I have just referred be correct, it is clear that pneumothorax, in its initial stage, must be an active process. Some force will be required to overcome the normal cohesion between the two layers of pleura, and to separate them. This must be obtained by expiration, and pneumothorax, therefore, in its initial stage is an expiratory process, and not essentially different in its production from surgical emphysema. As soon, however, as separation has been effected the elasticity of the lung will come into play, and air will enter the pleura until its retractility is completely satisfied, and, according to the observations of Donders (*loc. cit.*), this will continue until the lung occupies, in its collapsed state, not more than one-eighth of its original volume. Air, therefore, may enter, or fluid collect in quantity enough to occupy the space thus left in the pleura, without the development of any increased intrapleural pressure.

In considering the pleural pressures in pneumothorax, a sharp distinction must be drawn between the pressure during inspiration and that during expiration. The expiratory pressure will, of course, be always positive. Only when there is a large patent opening, so that air can pass freely out, will the expiratory pressure approach to zero. It will, however, differ widely in different cases, depending upon the force of expiratory effort.

With the inspiratory pressure the case is quite different. Air will continue to enter through the opening into the pleura until the pressure within, in the position of the deepest inspiration, is equal to that of the atmosphere. When this point is reached no more air can enter; and if, as is usually the case, the opening be valvular, so that no air can escape, the pressure on inspiration will remain at zero. If the inspiratory pressure now rises, some other cause must be at work, and in most cases this is found in the development of effusion, either serum or pus; and a positive inspiratory pressure may therefore be taken as indicative of the presence of fluid. The converse, however, is not true; for fluid may be present in considerable quantity, as already stated, and yet the inspiratory pressure be not raised above zero. Under one condition only could the inspiratory pres-

Digitized by Google

sure rise above zero without fluid—namely, when, after the closure of the opening, the body temperature had been raised several degrees; but as such a rise in temperature is nearly always due to the development of fluid effusion, a difficulty is not likely to arise.

The next point of interest is the respiratory oscillation—that is, the difference between the pressures on inspiration and expiration—measured, of course, during ordinary quiet, not forced, respiration. This has been variously estimated in health. [By Donders at 1½ mm. of mercury, by Hutchinson at 3 mm., by Adamkiewicz from 3 mm. to 5 mm., by Hegel and Spehl at 3·6 mm. (quoted Heynsius, xxix., 265; Pflüger's *Archiv. f. Physiol.*).] The majority of observers value it at about 3 mm. of mercury, or about an inch and a half of water. This is found to be the respiratory oscillation in many cases of pneumothorax. It is, however, often in excess of this, especially when there is dyspnœa, the excess being due then chiefly to the rise of pressure on expiration.

There are two conditions under which the respiratory oscillation in pneumothorax is observed to be even less than normal. In the first the opening is widely patent, and air passes without any hindrance in and out of the pleura; in the other the opening is closed, and the inspiratory pressure is high. What is observed in this latter case is this: on first introducing the trocar, before air or fluid has been removed, the respiratory oscillation is small, perhaps not more than half an inch of water; but after relief of the tension, as the inspiratory pressure falls, the respiratory oscillation increases often much beyond the normal. The explanation of this is, I think, to be found in the effect produced by the high pressure upon the opposite lung. This lung, by the raised inspiratory pressure, has been partly collapsed, and the walls of the thorax have been allowed to expand, so that they are in the position of deep inspiration. The high expiratory pressure prevents the normal elastic recoil of the lung on that—that is, the unaffected—side. As soon, however, as the pressure is relieved, the elastic recoil comes once more into play, and the respiratory oscillation increases.

The following selected cases of pneumothorax with effusion illustrate the statements which I have just made:—

CASE 1.—Male, aged twenty-two. Hydro-pneumothorax. Recovery.

		In. of water.
First paracentesis	Inspiratory pressure	= + 6⅛
	Expiratory „	= +13¼
	Respiratory oscillation	= 6⅛

The patient was an apparently healthy young man, of considerable muscular power. The high respiratory oscillation was due to dyspnœa, and depended chiefly upon the very high expiratory pressure. Forty ounces of serum removed.

		In. of water.
Second paracentesis	Inspiratory pressure	= + 6½
	Expiratory „	= + 8
	Respiratory oscillation	= 1½

The fall is observed chiefly in the expiratory pressure. Twenty ounces of serum were removed. From this time the patient rapidly improved, and left the hospital perfectly well. He has been frequently seen since, and he has been in active work for nearly three years. He appears in perfect health, and it is now almost impossible to say which was the side affected.

CASE 2.—Male, aged twenty-one. Hydro- (later pyo-) pneumothorax; death from rupture of an aneurysm of the pulmonary artery.

		In. of water.
First paracentesis	Inspiratory pressure	= + 1
	Expiratory „	= + 5
	Respiratory oscillation	= 4

Twenty-eight ounces of serum were removed.

		In. of water.
Second paracentesis	Inspiratory pressure	= + ⅛
	Expiratory „	= + 2⅛
	Respiratory oscillation	= 1⅛

Thirty-six ounces of serum were removed.

Subsequently an abscess formed in the seat of puncture, which was found later to communicate with the pleura. A free incision became necessary. Some days after this the patient suffered from severe hæmoptysis, and blood passed from the incision as well. Death resulted from exhaustion consequent on the hæmorrhage, and on post-mortem examination a ruptured aneurysm of the pulmonary artery was found.

CASE 3.—Male, aged twenty-two. Hydro- (later pyo-) pneumothorax. Death. A large opening into the lung was found.

		In. of water.
First paracentesis	Inspiratory pressure	= + 3½
	Expiratory „	= + 8½
	Respiratory oscillation	= 4½

Thirty-six ounces of serum were removed.

		In. of water.
Second paracentesis	Inspiratory pressure	= + 1
	Expiratory „	= + 6
	Respiratory oscillation	= 5

Hardly any fluid was obtained.

		In. of water.
Third paracentesis	Inspiratory pressure	= − ¼
	Expiratory „	= + ¼
	Respiratory oscillation	= ½

Fluid not reached.

Fourth paracentesis: Pressures the same.

Forty ounces of pus were removed.

The conditions were clearly entirely changed at the time of the last two paracenteses. The conclusion was drawn, from the small respiratory oscillation of a quarter of an inch only on each side of zero, that a large opening must have developed in the lung. The patient died shortly afterwards, and this was found to be the case.

CASE 4.—Male, aged twenty-four. Pneumothorax with sero-purulent fluid. Death.

Inspiratory pressure	= + 6¾	inches of water
Expiratory „	= + 8¼	„
Respiratory oscillation	= 1½	„

Thirty-four ounces of sero-purulent fluid were removed.

CASE 5.—Male, aged thirty. Pyo-pneumothorax. Death.

Inspiratory pressure	= + 1½	inches of water
Expiratory „	= + 2½	„
Respiratory oscillation	= 1	„

Eighteen ounces of pus were removed.

Subsequently pus discharged itself at the seat of puncture, and an incision was made. The patient died shortly after.

CASE 6.—Male, aged forty-six. Hydro-pneumothorax.

		In. of water.
First paracentesis:	Maximum pressure	= + 9

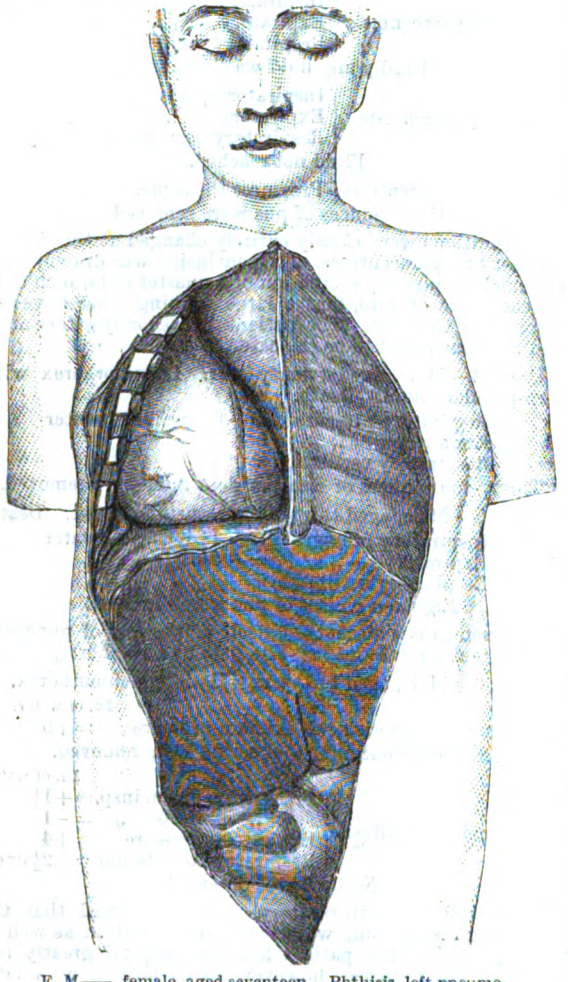
Seventy-four ounces of serum were removed.

		In. of water.
Second paracentesis	Pressure on ordin. insp.	= + 1½
	„ deep „	= − 1
	Expiratory pressure	= + 4
	Respiratory oscillation	= 2½ or 4½

No fluid was obtained.

The variations in inspiratory pressure showed that the opening from the lung was closed to inspiration as well as to expiration. The patient left the hospital greatly improved. He returned, however, about two months later with a discharging empyema. The side had fallen in greatly, so that the ribs were close together, and signs of phthisis had developed at both apices.

All the preceding cases confirm the statement made, that when the inspiratory pressure is positive the presence of fluid may be inferred. As already stated, however, the converse is not true—namely, that if the inspiratory pressure be not raised fluid is absent. The following case illustrates this fact:—



CASE 7.—Male, aged thirty-one. Pneumothorax with effusion. On paracentesis the inspiratory pressure was zero, but seventy-four ounces of serum were removed. After this the fluid was gradually absorbed, and the patient left the hospital feeling well, although the fluid had not quite disappeared.

Certain results follow from the alterations in pleural pressure just described, the most important and characteristic being, of course, the displacement of organs, especially of the heart. This displacement, it is known since Dr. Douglas Powell's experiments, is not due to pressure, but to the retractile power of the lungs themselves, and therefore is not necessarily associated with a rise in intra-pleural pressure; but it is clear that when the pressure is positive the displacement will be increased.

The heart, when displaced, is not, as was once supposed, rotated, but simply drawn or pushed bodily over. I append a drawing, for which I am indebted to my friend Mr. E. O.

Digitized by Google

Bark of Birmingham, a former resident medical officer at the Chest Hospital, Victoria Park. In this it will be seen that the relation of parts is the same as when the heart is in its normal place; the only twisting or rotation which takes place—and it is but very little—is that necessitated by the curving of the ribs. The displacement is the same in kind, whether it be to the right or to the left side, and whether by air or by fluid.

E. M——, female, aged seventeen. Phthisis, left pneumothorax. The chest was opened by an incision down the middle line of the sternum, which was sawn through, and the costal cartilages on the right side having been divided, the front wall of the right pleural cavity was removed, leaving the left side unopened. At the upper angle of this opening was a large, rounded, tense tumour. This was the left pleural sac distended with gas and pushed considerably beyond the right border of the sternum, nearly reaching the end of the second rib. Directly below this was the pericardium, on opening which the heart was seen to be entirely on the right side of the chest, the apex being behind the right border of the sternum; the front of the heart consisting of the right ventricle, with a narrow border of left; scarcely any twisting on the axis, but the mediastinal structures, bronchi, and great vessels, all pushed over to the right side, the trachea passing nearly behind the right sterno-clavicular articulation. The right lung was only visible at the lower external angle of the opening, where the anterior border slightly overlapped the pericardium. On opening the left side of the chest a considerable gush of air took place, and the tumour of the left pleura became flaccid, but did not entirely recede behind the sternum; the heart returned more than an inch towards the left side. The left lung was adherent to the chest wall posteriorly down to the third rib; anteriorly and latterly the lung was free, except that the small tongue of the upper lobe, which lies ordinarily in front of the heart, had a firm band passing from its apex to the pericardium. There were two openings in the pulmonary pleura communicating with cavities in the lung. The pleural cavity contained a considerable quantity of pus, and the costal pleural was thickened, and covered in many places with pyogenic membrane.

In spite of the extreme displacement of the heart which occurs, cardiac murmurs due to displacement are, I believe, very rare. I have also been unable to satisfy myself of the actual existence of the sharp bending in the vena cava which the late Dr. Moxon described in displacement, and to which he referred some of the cases of sudden death in large pleuritic effusions. When the intra-pleural pressure is high, the veins running upon the inside of the thorax may be compressed, and the interference to the circulation through them will show itself by distension of the superficial veins of that side, and also by distension of the veins of the arm and neck. It might be supposed that when air or fluid are present together in the pleura, the air would probably be readily absorbed as the pressure arises. This, however, is by no means the case. I shall return to this point later.

One result attributed by many writers to great distension in pneumothorax my own observation does not confirm. It is stated that by the high pressure the percussion note may lose its tympanitic character, and become muffled or even dull. I have never been able to obtain the slightest evidence at the bedside to support this assertion, and a few experiments I have made go far, in my opinion, to disprove it.

The access of pneumothorax is usually sudden, and marked by characteristic severe symptoms, but in some cases these initial symptoms are slight, or even, it may be, entirely absent. These cases are described as latent pneumothorax. They are met with usually in the course of advanced phthisis, for to a bedridden patient it matters little whether a lung be useless on account of phthisis or because of the collapse which results from pneumothorax. Latent pneumothorax is, however, sometimes met with in phthisical patients who are not in bed, and even occasionally, though of course much more rarely, in the apparently healthy; that is to say, pneumothorax is sometimes discovered in these cases where there is nothing, or very little, in the clinical history to fix the date of its access. I know of no satisfactory explanation of the absence of initial symptoms in these cases, but I have myself met with it a few times.

The prognosis of pneumothorax is, of course, unfavourable. When it occurs in the ordinary course of phthisis, the mortality is very high. My own statistics show that about 90 per cent. of these cases die within the first month.[16] Weil's mortality-rate is lower—namely, about 50 per cent.[17] It is difficult to attach much statistical importance to small numbers, and the truth probably lies somewhere between these two extremes. Each case must, however, be judged upon its own merits. In any particular case the prognosis will be determined chiefly by the cause of the affection, and by its effect upon the patient, and next by the character of the effusion which may develop.

I wish, however, now only to speak of the cases in which recovery occurs. This may take place in one of two ways: either by the gradual conversion of the pneumothorax, through the development of fluid and the disappearance of the air, into a case of fluid effusion, which heals in the usual way; or by the simple disappearance of the air without the development of any fluid at all.

In the first group of cases the exudation is, of course, usually serous, but not invariably. In the case of a man, aged twenty-two, suffering from pneumothorax, on the first paracentesis pus was withdrawn. On the second paracentesis, about a fortnight later, the fluid was found to be sero-purulent, and finally it became serous. Recovery was ultimately complete.

The second class of case—namely, that in which recovery takes place without any effusion—is, of course, much less common, but still not altogether rare. I described, in the Clinical Society's Transactions, vol. xvii., p. 56, one such case, and I collected records of twenty-four other cases from literature, although the list did not pretend to be complete. Since that paper was written I have seen two or three other instances myself, and a few more have been reported, so that the number of recorded cases of this kind is now not very small, and as attention has been directed to them it is probable that this number will be soon further increased.

This rapid removal of air is familiar in experimentally produced pneumothorax. It is, in fact, I believe, difficult to maintain an artificial pneumothorax long in a healthy animal, because the air so quickly disappears. Fluid effusion may also in like manner be rapidly removed, and in both cases alike the lung may very rapidly re-expand. The common explanation given of the re-expansion of the lung after fluid effusion is not altogether satisfactory. The walls

Digitized by Google

of the chest fall in; adhesions, it is assumed, have formed across the pleural cavity, and as these contract the lung is pulled out so as to be again in contact with the parietes of the thorax. This may be the correct explanation, but it seems improbable, for adhesions are quite as likely to form over the lung and bind it down, and, in fact, the existence of adhesions in this position is often assumed to explain cases in which the lung has not expanded. This theory assumes, moreover, that the pleural cavity must, as a matter of course, after fluid effusion, be obliterated, and I do not think that this is always the case in the pleura any more than it is the necessary and invariable consequence of effusion into the joints. Whether this explanation be sufficient or not for the cases of long-standing pleuritic effusion, it is clearly inadequate to explain the cases of rapid absorption of fluid referred to. Cure by the formation and gradual contraction of adhesions is slow, and requires many weeks or months to complete itself, but in the cases we are now considering recovery is often accomplished in as many days.

What is the mechanism, then, by which the lungs in such cases are re-expanded? They collapse, it is known, by virtue of their own elasticity, with a force equivalent to about 7 millimetres of mercury. If they are to be re-expanded, some force is required for the purpose which shall be greater than this. When they are brought out so that the two layers of the pleura are in close contact, cohesion comes into play, as I have shown, to keep them out, but to get them so far a force greater than 7 millimetres of mercury will be necessary. Where is this force to be found?

The question, perhaps, is simpler in the case of fluid than it is in the case of air. The fluid may be removed in many ways: by absorption, by transudation, or by the pump-like action of the respiratory movements upon the lymphatics of the pleura. The existence of this last process as a factor in the removal of the fluid depends upon the demonstration of stomata in the parietal and visceral layers of the pleura. Recklinghausen first demonstrated stomata on the peritoneal surface of the diaphragm; Dybkowski in the costal pleura; and, although their real existence has been denied recently by Sappey, Klein, in his work on the "Lymphatics of the Lung," has no doubt of their existence, and thus describes the part they take in absorption: "It is quite clear," he says, "that the respiratory movement of the lungs is a factor that plays a most important part in the process—that is, of absorption by the lymphatics. When the lungs expand, as during inspiration, it will necessarily have the effect that the stomata of the surface are opened widely, and that the inter-muscular lymph spaces of the lung (of the guinea-pig), as well as the proper lymphatic vessels of the pulmonary pleura, become distended. Under these conditions the lymphatic system will become filled with material that happens to be in the pleural cavity, and that is able to pass through the stomata. During expiration, on the other hand, the stomata as well as the lymphatic spaces and proper lymphatic vessels will become compressed, so that their contents will be discharged into the efferent trunks." He further states elsewhere that the existence of stomata is actually demonstrated in inflammation by the bands of coagulated fibrin which are found plugging them. In the case of pathological effusions into the pleura this arrangement of the lymphatics cannot fail to be of the highest importance. It is often observed that a large effusion remains stationary for a long time when left alone, but that removal of a part of the effusion by paracentesis is followed by a rapid disappearance of the remainder. Paracentesis is followed, as I have shown above, by a return of the respiratory movements, which had been more or less impaired by the large effusion, and the consequence of this will be that the lymphatic pump will be restored to action. It is evident that in this process we have a power sufficient of itself to produce the force requisite for the re-expansion of the lung.

In considering the removal of fluid from the pleura, that peculiar property of the lung must not be forgotten of which mention has been made. I refer to the ready permeability of a still air-tight lung to fluid under pressure, so that it is possible that a part of the exudation may be actually squeezed through the lung as through a sponge, and, when it has reached the bronchi, may be got rid of partly by expectoration and partly by absorption. Perhaps this is an explanation of the so-called profuse watery bronchitic expectoration occasionally met with in large pleuritic effusions, and which is usually attributed to pulmonary congestion. I think this theory might be tested by chemical examination of the sputum, for such a transudation would probably be more richly albuminous than that of ordinary bronchitis. It is not likely, however, that this process can be of much importance in ordinary cases, on account of the frequent absence of any considerable pleural pressure, and because of the collapsed condition of the lung on the affected side. It may, however, play its part in relieving tension to some extent, and aiding in this way the lymphatic pump to get once more to work.

Lastly, we have to consider the removal of fluid by absorption, with especial reference to the consideration whether it may be capable of producing the force requisite for the re-expansion of the lung. I do not know of any experiments bearing directly upon this question—that is, the question of the force developed by absorption within the body. Exudation (which, I suppose, may fairly be regarded as the counterpart of absorption) may take place under considerable pressure, for proof of which we need not go beyond the pleura itself, as the pleural pressures in many cases of effusion demonstrate. We have only to imagine the process reversed, and more than the required force will be available.

It is possible that, so far as mere exudation goes, there may be no essential difference between dropsy and inflammation, and that in both the exudation may be due to obstruction, with this only difference, that in dropsy the obstruction has usually a more or less distant origin, and in inflammation a local cause in the inflamed part. If this be so, the cessation of inflammation will remove the obstruction, no more exudation will occur, and the effusion will be ready for absorption. If, as Draper assumes,[18] in opposition to the commonly accepted doctrine, the interchange of gases in the blood in the capillaries is sufficient—as I must confess it appears to me to be—to produce a current onwards in the blood, we may have in this a force of some magnitude to aid in absorption, a kind of capillary aspiration, if it may be so termed. At any rate, in the absence of direct experiment, we may, I suppose, assume that we may have the same force available in disease to remove pathological fluid from the pleura which, in health, is active to keep the pleura empty.

The removal of gas from the pleura is a still more complicated problem. The conditions we have to deal with are these two gas-holding cavities: first the lungs containing gas of a tolerably constant composition; secondly, the pleura containing gas which differs, in many respects, from that in the lungs;—these two cavities being separated by a complex membrane richly supplied with bloodvessels. We know that the gas is quickly and completely removed from the pleura, and under such conditions that, at the last, not less than 7 millimetres of negative mercury pressure is produced. The process by which the gases may be removed are these—diffusion, simple absorption, and absorption aided by chemical combination:

The percentage composition of the air in the vesicles of the lungs may be taken to be the following:[19] N=79·557; Co^2=4·380; O=16·033, and this probably remains fairly constant, the exchange between it and the atmospheric air in the larger tubes being provided for to a great extent by diffusion.

The air in the pleura varies in composition. If the air enters from without through a wound in the thoracic walls, it is of course to begin with simply atmospheric air. If the air enters through a perforation in the lung, it will have the composition of the air in the vesicles as given above. If the openings remain patent, the composition of the pleural gas may change but little; if, however, the openings be closed, changes in its composition at once take place, and these changes have been used to determine the question of the patency of the perforation. The earliest analysis of the gas in the pleura in pneumothorax was made by Dr. Davy,[20] who found that the O varied from 2·5 to 5·5, the Co^2 from 6·0 to 8·0, and the N from 88 to 90 per cent. More recent analyses[21] show that after remaining for some time in the pleura, the oxygen almost completely disappears, while the carbonic acid and nitrogen increase, the former very considerably. An analysis of Demarquay's[22] will illustrate this:—O = 0·49; Co^2 = 11·16; N = 88·35.

There are, so far as I know, no systematic analyses of the gases made during the stages of disappearance of a pneumothorax, so that the subsequent changes can be only a

Digitized by Google

matter of inference. In the end, however, all the gas, whatever be its composition, is removed. It is evident, however, that diffusion simple is quite inadequate to explain even those changes which are known to occur; for although at a given time, owing to unequal rapidity of diffusion of the different gases, the relative composition of a mixture might be changed, diffusion could in the end only lead to uniform composition of the two exposed mixtures, and the gases in the pleura could not therefore by diffusion be made to disappear. Gréhant[23] has further shown by experiment that, when the circulation is intact, little, if any, interchange of gases takes place through the pleura. If his observations be correct, it follows that, in the removal of gas from the pleura, we have to deal only with the same processes as are concerned in the exchange of gases in the lungs; and that what we have to consider is the action of circulating blood upon the gases contained in the pleura. In these processes, diffusion enters only so far as to provide for the passage of the gas into the blood-plasma, where the other processes —namely, absorption and chemical combination—come into play. The only difficulty here is that the blood is exposed on two sides to gases of different composition; and it might be supposed that, when the tension of gases in the pleura became less than that of the same gases in the vesicles of the lungs, no further removal of these gases from the pleura would occur.

Although the blood absorbs oxygen, carbonic acid, and nitrogen, still these gases were not all found to obey in the blood the laws which govern the absorption of gases in fluid, and it was inferred that the gases entered into loose chemical combination in the blood. This has been proved in the case of oxygen and carbonic acid, and is possible also, though to a much less degree, in the case of nitrogen.

The complete disappearance of oxygen from the pleura after pneumothorax is illustrated by two series of physiological observations. Analysis of the gases contained in the lungs after suffocation by obstruction of the trachea or bronchi shows that the oxygen is reduced to almost exactly the same amount as that in the analysis given of the air in pneumothorax — namely, about 0·4 per cent. Again, in experiments on respiration in a closed space, analysis shows a similar complete absorption of oxygen from the air of the chamber in which the animal is confined. There is, therefore, no difficulty in accounting for the complete disappearance of the oxygen from the pleura.

The carbonic acid, though partly absorbed, exists similarly in loose chemical combination both in the serum and in the cells of the blood; but there is this difficulty with carbonic acid, that while oxygen is naturally absorbed from the air in respiration, carbonic acid is naturally returned to it; and the analysis of the gas in pneumothorax seems to show that the carbonic acid does at first actually increase in amount, not only relatively to the nitrogen, but absolutely, so as to even reach 12 per cent., an amount considerably in excess of the carbonic acid tension in venous blood. These facts admit, however, of another and, I think, a more probable interpretation. If, as we suppose, the changes between the blood and the gas in the pleura are the same as those between the blood and the air in the lungs, there will be for every volume of oxygen absorbed an almost equal volume of carbonic acid discharged; so that in the end, when all the oxygen has disappeared, its place should have been taken entirely by carbonic acid. There ought, on this assumption, to be about twenty volumes of carbonic acid, the nitrogen remaining the same, but none of the analyses given show more than 12 per cent. The conclusion, therefore, may be drawn that the difference—namely, eight volumes—has been already absorbed. This interpretation has the advantage of removing the difficulty previously referred to, of the apparent increase at first of the carbonic acid.

A similar apparent accumulation of carbonic acid takes place, it is stated, in the vesicles of the lung, when the bronchus leading to them has become plugged, the lung in that part, on the absorption of the carbonic acid, becoming atelectatic. It is, however, in the end all removed. As experimental evidence of this is quoted the complete atelectasis which is produced by suspending a lung in water after it has been filled with carbonic acid.[24]

The nitrogen exists in the blood, it is believed, chiefly in simple solution, although the possibility of weak chemical combination cannot be absolutely excluded. The ease with which the nitrogen may be removed from the blood is demonstrated by the experiment of allowing an animal to breathe an innocuous gas containing oxygen, but free from nitrogen. Under these circumstances the whole nitrogen is discharged from the blood. According to Reynault and Rieset, there is naturally found in the expired air of health a slight excess of nitrogen; but it is also shown by other observers that under certain conditions nitrogen may be absorbed to some extent during respiration.

Now, although I do not know of any experiments which actually demonstrate the force which may be developed by the absorption and chemical combination of these gases in the blood, still it is extremely probable that in both of these processes there may be a far greater force developed than that which we require for the re-expansion of the lung. Into this problem the question of time hardly enters; for, if these processes be active at all, whatever influence time may have will be all in their favour. If, however, we may measure the force of interchange by its rapidity, it is clear that we must have great forces to deal with; for we find that in the twenty-four hours no less than 900 grammes of carbonic acid are excreted and 744 grammes of oxygen absorbed; and, in spite of this, there are contained in the entire blood of the body at any given time a total quantity of only 4 grammes of carbonic acid and oxygen combined.[25] Such a statement shows the extreme rapidity with which the exchange of gases is carried on; and we may, I think, fairly argue from the rapidity to the force of exchange.

The preceding speculations are necessarily somewhat crude; still the facts which have to be explained are well established—namely, the rapid disappearance of the air and fluid, and the consequent rapid re-expansion of the lung. Incomplete as is our present knowledge of the actual processes concerned, it is evident that in many of them there are sources of power sufficient to provide the force of which we are in search.

I wish that I could have spoken of the treatment to be adopted in the different forms of pneumothorax. There is much to be said upon this question. I must, however, leave this and many other interesting parts of the subject untouched, for the time at my disposal has reached its limit.

When I selected pneumothorax as the subject of this lecture, I did so because it had long been with me a favourite clinical study. I was aware that much had been already done, but I did not realise how much still remained for investigation. I can hardly hope that in this short lecture I have been able to throw much light on the many complicated questions which have arisen, but I shall be content if I have rendered more visible some of the shadows which still rest upon this field of knowledge.

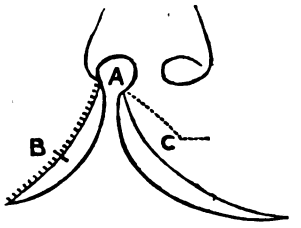
NOTES UPON THE OPERATION FOR HARE-LIP.

By EDMUND OWEN, F.R.C.S.,
SURGEON TO ST. MARY'S AND THE CHILDREN'S HOSPITALS.

To obtain the most artistic result in the operation for hare-lip several practical matters demand attention; chief amongst them is this, that the line of operation be so planned that the cicatrix eventually prove as inconspicuous as it is possible for it to be. It should not descend straight from the nostril to the free border of the lip or it will be sure to invite attention, especially where it traverses the mucous border; and if the operation be done in the old-fashioned way the lower end of the linear scar is apt to be permanently indicated by a triangular notch in the free border of the lip. Then, the healing should be prompt, and the line of union thick and strong, and there should be eventually no white dots upon the surface marking the passage of hare-lip pins.



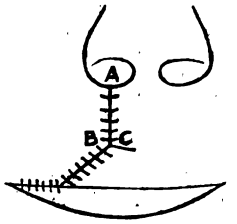
Supposing that the cleft extend into the right nostril, as in Fig. 1, the operation is begun by paring off the mucous membrane from the right side (but without removing any skin) through the whole thickness of the lip, and that not in the vertical direction only, but outwards almost to the angle of the mouth. (Arteries are best secured throughout the operation by forci-pressure forceps.) The mucous border of the lip on the left side of the cleft is to supply the lower

[25] Ibid., p. 281.

Digitized by Google

border of the right side of the lip; and for this purpose it does not suffice to bring a thin tail of mucous membrane across the cleft—a thick, bold, serviceable flap is needed. This is got by making an incision through the lip with a fine scalpel, from A to C; then, when the sides of the cleft are drawn together by the finger and thumb, the raw surfaces A B, A C are brought together in the vertical line, and are secured by four or five interrupted sutures of fine wire which pass deeply through the substance of the lip, whilst the full part of the labial flap is brought across beneath the vertical incision to form the prolabium. The rest of the flap, which is not merely mucous membrane, is brought to the right side of the lip, being trimmed and adjusted as circumstances demand. (Fig. 2.) Each case may need some special modification of procedure—"one must cut one's coat according to one's cloth,"—but the general plan of the operation as described above remains. There is an economy of tissue, for the mucous membrane on one side of the cleft only is

FIG. 1.



Single hare-lip; lines of incisions shown by dots.

wasted; that of the more promising side, with a good deal of the lip tissue, is brought down to form the border of the new lip. It may be that some weeks after the wound has soundly healed a finishing touch or two may be needed.

I have now altogether given up the use of hare-lip pins in the operation, and since doing so I have dealt with some of the very worse double clefts that I have ever seen, and to my entire satisfaction. The pins were originally used, no doubt, to keep the strain off the sutures, but the introduction of the improved waterproof strapping has rendered them entirely superfluous. A great disadvantage of the pins was that they were apt to leave the points where they passed through the skin marked by permanent and unsightly scars. To diminish the risk of this to the utmost I had been in the habit of withdrawing them at the end of twenty-four hours, but more recent experience shows that one can obtain better results by discarding them altogether. The sutures should be of fine silver wire passed deeply, and of

FIG. 2.

Lines of incisions adjusted by fine sutures, no pins being used.

horsehair which has been soaked in warm carbolic lotion; the latter answer particularly well for adjusting the mucous membrane. Sutures have also to be used freely and deeply along the dental surface of the vertical and oblique wounds; they should be arranged as carefully as are those upon the dermal surface. They complete the adjustment of the edges, they steady the tissues, and they prevent food and the tip of the tongue from getting into the wound. For applying them the lip must be thoroughly everted. On a few occasions I have met with a hare lip after operation in which the bond of union was only of the thickness of the skin; I apprehend that if this posterior set of sutures had been used the adhesion would have been through the whole thickness of the lip. I have never had my attention called to scars upon the tongue or gum from irritation caused by these sutures, and consequently I leave them to find their own way out; the sutures upon the front of the lip I begin to remove on the second day.

When the operation is finished I cover the lip with a scrap of absorbent wool, and, drawing the cheeks well together with the finger and thumb, I steady them by a piece of waterproof strapping, the wide ends of which reach nearly to the ears, whilst the middle part is narrowed in proportion to the depth of the lip.

It is to be noticed in Fig. 1 that the line of incision A C is prolonged for some distance upwards and outwards through the lip; unless this be done the border of the lip does not lie level, a slight kink being found in it. But on making this secondary incision the flap comes smoothly across.

SOME BACTERIOLOGICAL OBSERVATIONS IN CONNEXION WITH SUMMER DIARRHŒA.[1]

BY H. TOMKINS, M.D., B.SC., SAN. SCI. DIP.,
MEDICAL OFFICER OF HEALTH, LEICESTER.

THE mortality caused by summer diarrhœa is at first sight almost staggering to those who pay little heed to vital statistics. During the three months ending September, last year, no less than 15,900 deaths were attributed to diarrhœa in England alone; had but a quarter of this number been caused by any other disease, not only the professional but the public mind would have been startled thereby. Then why this comparative apathy that exists in regard to diarrhœa? The reasons are various. First, the very large proportion of these deaths occur amongst infants and young children; in some of our large towns a veritable slaughter of the innocents occurring annually in the summer months. Probably another reason is to be found in the fact that diarrhœa is not one disease, but is in many cases only a symptom or accompaniment of other ailments, and has not one common cause, but both in etiology and pathology presents much variety. Even its place in our nomenclature of classified diseases has been, and is, subject matter of dispute; for whilst generally it is agreed that it should be placed in the zymotic group, reasons have been adduced to show that it does not rightly belong here. One feature of much interest is the varying prevalence and fatality of this disease, in different towns, and in different parts of the country, and an inquiry directed especially to this point has been in progress under the direction of the Local Government Board for some years past, without, up to the present, yielding any satisfactory explanation of the same; and as yet no results have been published, though such men as Drs. Power, Ballard, Klein, and Cash have been engaged more or less in the work. As to the immediate cause or causes concerned in its production the ground is no more clear. Heat, dampness, improper food, artificial feeding, maternal neglect, wet subsoil, dense populations, peculiar geological or meteorological conditions, congenital debility, foul air, organic emanations, &c., have one and all been put forward as its cause or causes, and doubtless most of these play a certain part in its production, but very little consideration will serve to show that none of these alone afford us a solution of the problem. Of all these, the only one that exists constantly, and without which the disease in epidemic form is not met with, is a high temperature; and yet that heat alone is not the sole cause is seen on comparing different towns and districts where the temperature, as registered by the thermometer, is practically the same. For instance last summer, whilst in Wiltshire, Dorset, Hereford, Shropshire, Rutland, Westmoreland, and North Wales the death-rate was less than ½ per 1000, in Middlesex (extra metropolitan), Warwickshire, Leicestershire, and Yorkshire it was seven times as fatal. Or, taking the large towns, in Bristol the mortality was only 1 per 1000; in Huddersfield and Halifax only about 1·5, and in Derby 2·5; whilst in Salford and Preston it was nearly 5½ per 1000, in Leicester 6·23, and in Norwich 8·24. It cannot be supposed—and, indeed, is easily disproved—that the variations in feeding, or maternal care, or density of population in the above places are such as to cause a mortality nearly ten times as great in some of these towns as in others. Another fact which has been too much lost sight of in connexion with this subject is, that, although it is young children

[1] A paper read before the Manchester Medical Society.

Digitized by Google

who chiefly die, the disease is by no means confined to them, and I can show that for every case of diarrhœa occurring amongst children under five years of age there are probably four times as many above that age who suffer in the same way. In Leicester, out of 9700 patients, of whom particulars have been obtained, only 2400 were children under five years old. If we come to consider and examine more closely the prevalence of this disease in the various districts of a large town, after making due allowance for the influence exerted by all the above-mentioned supposed causes, we are led to the same conclusion as when comparing different towns with each other—i.e., that there appears to be some factor at work in some districts which is absent in others, and the theory that it is due to some form of germ life has been advanced with considerable plausibility. For even those who put forward as the cause such influences as over-crowding, foul atmosphere, organic emanations, and sewer air must admit that the deleterious effects of these things is not simply because the air is foul, or the emanations organic, or the air derived from sewers, but because each and all of these are laden with something, probably the germs of bacterial life, and to which germs the resulting ill-effects are most probably due. So wonderful and interesting are the discoveries made of late years respecting the connexion of disease with these low forms of life, and so captivating is the study of them, that, undoubtedly, we are in danger of going too far and pushing theories further than we are warranted by ascertained facts; it behoves us therefore to sift and weigh well all evidence or observations brought forward in support of a bacterial origin of any disease, and no one is more conscious of the incompleteness and points open to criticism in the few facts which I am about to notice than I am myself.

Leicester, the town to which I am medical officer of health, stands pre-eminent amongst English urban populations in two respects: first, it is the headquarters of the opponents of compulsory vaccination, the vaccination laws being to-day practically in abeyance there; and, secondly, it has for many years stood above all the other large towns for the prevalence of, and mortality from, summer diarrhœa, thus affording a large field for the observation of this disease. This unenviable notoriety has attracted the attention of the Local Government Board, who have sent experts to make special investigation into the subject. By local observers also much time has been expended and work done, with a view to ascertain what are the factors to which this excess of diarrhœa is due. But it would take up too much time to attempt to go through this work in detail. The late medical officer of health, indeed, after paying much attention to the subject, gave it as his opinion that the cause was to be found in the emanations from the sewers, which in the lower parts of Leicester are in a notoriously bad state, being flat, without fall, too small in size, most of them never free from deposit, and often liable to be overfilled and flow back into the cellars and low-lying parts of the town; but actual proof of this theory is not forthcoming. Leicester is situated in the valley of the Soar, with rising ground to the east and west. All the older part of the town lies in the hollow or flat district, whilst the newer parts (as the town has extended) are built on the rising hills on either side, these being at the highest point some 100 feet above the low-lying district. The soil (alluvial drift) in the flat part is variable in character, much of it being clay, whilst irregularly distributed patches of sand and gravel are also met with. It is in this lower, flat part of the town where diarrhœa is most prevalent; and finding that, for years past it was in this area diarrhœa most prevailed, I thought it well to try to ascertain whether the air of this district would yield to experimental research any definite results, or different ones from those of the air in other parts; at the same time to examine the organs of the body in fatal cases for any corroborative evidence as to the cause of the disease.

By the employment of the methods of cultivation now in common use by bacteriologists, I believe I have arrived at a few certain definite results. And here I may remark that although during last summer more than 200 deaths have occurred, and notwithstanding that I have received the hearty co-operation of the medical men of the town, in only five instances have I been able to obtain a post-mortem examination within a sufficiently short time after death to be of any use for the purposes here required, for unless the examination of a body be made within at most six hours from death, any results obtained are quite unreliable. Of the chemical and pathological features of the disease I have nothing new to say, but it may be noticed, in passing, how very shrivelled and pinched in many cases is the expression after death from this disease, reminding one much of the faces seen in cholera. Another fact that arrested my attention, was the comparatively slight naked-eye pathological changes met with. The spleen, the kidneys, liver, &c., were apparently normal; in a few instances the mesenteric glands were somewhat enlarged, but by no means constantly so. The chief lesions were seen (as of course might be expected) along the mucous membrane of the intestinal canal; but very different were these to those met with in typhoid fever. The inflammatory changes extended more or less throughout the entire length of the intestinal canal, being most severe along the ileum. Small ulcers were in most instances present, but there was none of the localisation of these to Peyer's patches, as in enteric fever, nor was the cæcum found to be affected more than other parts of the canal.

The general results of the examination of the various organs, with a view to ascertain the presence or otherwise of micro-organisms may be summed up as follows. From the blood (taken from the heart) no results were obtained, with the exception of once doubtfully from the right ventricle. From the spleen no cultivations could be obtained. From the mesenteric glands three of the cases furnished growths. From the kidneys abundant growths were obtained. From the ulcerations in the coats of the intestines (as of course was to be expected) the growths were abundantly profuse. From the first growth of micro-organisms obtained successive cultivations were made, with a view, if possible, of obtaining a purer growth, as the original ones were very mixed, containing micrococci and bacilli of various forms and sizes, but the attempt was not very successful. The material chiefly used in the cultivations was nutrient gelatine, this being found best adapted for that purpose. The temperature at which the cultivations were carried on was about 20 C. (68° F.), and a difference was observable in the rate of growth between the three sources—that is, between the growths from the intestine, the glands and the kidneys. In those from the intestinal coats the growth was more rapid, so that within three days the whole of the gelatine had become used up and liquefied, and the liquid swarming with micro-organisms. In those from the kidneys and mesenteric glands the rate of growth was much slower, but the changes that could be seen taking place from the point of inoculation were the same in character, the mass slowly becoming fluid, until at the end of a week no difference was to be seen between these and the former. The resulting growths from the intestines, kidneys, and mesenteric glands respectively, examined microscopically, showed but little difference. The photographs shown give some idea of the organisms seen. The bacilli, when compared with those of Asiatic cholera, are shorter and thicker. The reaction of the gelatine in each case becomes markedly alkaline; and one other fact worth notice is that in all there is developed a powerful offensive odour, even to the fourth and fifth generation, the latter of which cannot contain more than the two-millionth part of 1,000,000 of the original inoculation, and yet with this immense dilution the odour is as characteristic as in the first growth. From this we may to some extent realise the enormous power of reproduction these micro-organisms possess, seeing that in these tubes before you now swarming with microbes only a many-millionth part of the original material can possibly be present.

But probably of much more significance than the foregoing are the results of the examination of the atmosphere. I have examined the air of the streets of the lower parts of the town, air from the sewers in the same district, and compared it with the air of the higher districts where the disease is comparatively absent, with the following results:—Examined on the same lines as before by means of cultivations in nutrient gelatine, the air in the streets of those parts of Leicester where the disease most prevails, and where the sewers are in the worst condition, as to cleanliness &c., the number of organisms per cubic metre, varied from 2000 to upwards of 5000 or 6000, the latter being obtained from air from sewer ventilators in the middle of the streets. Whilst in the air of the more open and higher districts they varied from 60 or 80 to 800 or 900 per cubic metre. The growth of these was slower than in those cultivations derived from the organs of the bodies, but with the air from the sewers the gelatine was ultimately liquefied in the same manner, and in these cultivations an odour was perceptible

Digitized by Google

of the same offensive chraracter, but much slighter in degree to that before mentioned.

Thus far all that has been shown is that in the organs of the body after death, and from the air, &c., certain microbes have been obtained, and that these have been artificially cultivated in nutrient media; but no direct evidence is forthcoming to show their connexion with the disease. I am, however, able to assert from actual experiment that a very small dose of these artificially cultivated microbes will produce a smart attack of diarrhœa; and although it is far from being proved that this diarrhœa is the result of some form of bacterial life, as the four essential conditions for any such proof are not yet forthcoming—i.e. (1) the presence of a distinct and specific organism in the blood or tissues of those suffering from the disease, (2) the artificial cultivation of these apart from the body, (3) the production of the disease by introducing these into a healthy body, &c., and (4) the presence of the same organism again in the body when such disease is introduced,—yet I would submit that one is justified in saying that there is evidence to connect these organisms with the prevalence of the disease; and although this slight contribution to a most obscure and difficult subject is little more than preliminary to the complete study of the etiology of summer diarrhœa, and is open to criticism at every point, I have thought it not out of place to bring together, as it were, to a focus what little in the intervals of other work I have had the opportunity of doing.

Town Hall, Leicester.

A CASE OF HYDROPHOBIA AND A CASE OF TETANUS.

BY H. HANDFORD, M.D., M.R.C.P.,
PHYSICIAN TO THE NOTTINGHAM GENERAL HOSPITAL.

W. P——, a powerfully built carter, aged thirty-two, was admitted under my care into the Nottingham General Hospital, at 8 A.M., on Feb. 3rd, 1887, said to be suffering from hydrophobia. He had been bitten by a stray dog four months and a quarter previously. No further information could be gained about the dog except that it was not known in the neighbourhood in which the patient lived. The wounds were on the back of the third and fourth fingers of the right hand; they were not cauterised. He treated them with domestic remedies, and they healed in a week or ten days. The scars were quite evident, and had not become painful or irritable. When I saw him a few hours after his admission and examined him, though I led him up to the subject several times, he markedly avoided any mention of his having been bitten, or of his difficulty in swallowing, until directly asked. There was a very evident unwillingness to talk or even think of the subject. This at the time seemed to me to point strongly in favour of the genuine nature of the disease, for at the outset there were many difficulties in the diagnosis of hydrophobia, which had been first made by the patient himself before coming to the hospital. He had been a soldier, had had "fever" in India, and had been very intemperate. His mother died insane, and a brother has "fits." There was some doubt whether the patient had been drinking for the previous fortnight, during which time his wife said he did not seem in his usual health, but he did not speak of the bite. The patient himself said that three days before his admission he began to feel ill and thought he had a "cold." He was sleepless, restless, dizzy, and had momentary losses of vision. He consulted a medical man, who prescribed for him. After he returned home, as he was washing, he screamed directly the water touched his face. Shortly afterwards he noticed some difficulty in swallowing. He then made the diagnosis of hydrophobia for himself, went again to his doctor (whom he had not previously told either of the bite or of his difficulty in swallowing), and he confirmed it. A few hours later he walked to the hospital and asked to be admitted. He complained of difficulty of swallowing, and of a feeling of constriction over the upper part of the sternum. His expression was very anxious, eyes rather wild and staring, and he spoke with an appearance of enforced calmness. The temperature was normal; pulse 56, and quite regular; *respiration 22, and markedly irregular*, being frequently interrupted by deep sighs. My attention was directed to the character of the respiration by my colleague, Mr. White, whose experience extends to six or seven cases, in all of which irregularity of respiration was very noticeable. There was no huskiness or alteration of the voice, and no frothing at the mouth or spitting till a few minutes before death. His tongue was fissured, soft, flabby, and coated in patches with a thin white fur. He complained of loss of appetite and thirst, and had taken very little food for three days. He vomited several times the day before his admission. His urine was rather concentrated, sp. gr. 1024, and contained no albumen. At 10 A.M., two hours after his admission, the case was taken by Dr. Williams, and much of the following is taken from his notes. The patient was quite rational and could give a clear account of his illness. He asked for something to drink almost as soon as he came in. He would not let the nurse hold the cup, but grasped it himself quietly and firmly and swallowed the water at one gulp. During this act he became much excited. He would not have more than a tablespoonful of water in the cup at a time. He said he had no difficulty in swallowing, all his difficulty being in getting the cup to his mouth. When he was about to be washed, as is usual, he became much excited, and said to the sister of the ward, "Don't bring water near me." He asked to be sponged instead, but said if he had to be washed he would do his best not to scream. The noise of pouring out water at this time did not affect him. When washed he shuddered and sighed like a person in a cold bath, and turned his head away from the water, but was otherwise unaffected till his face was to be washed, when he asked for the sponge and himself rubbed his face violently. In doing so he squeezed out a few drops of water, which trickled down his face and caused a slight convulsion. When I saw him at mid-day he was quite calm and rational. On my requesting to see him drink, he asked me to stand away, turned his head from the locker on which the cup stood, reached out his hand, seized the cup, *and brought it rapidly to his mouth with very irregular, jerking movements*, took a large mouthful and swallowed it with marked effort, accompanied by very slight facial spasm and some *general excitement*. The process of swallowing was much like that of a child taking disagreeable medicine. There was nothing that one could fairly call a convulsion at this time, but there was probably incoördination of the muscles of deglutition. At 8 P.M. I saw him again, and he said he felt much better. His temperature remained normal, his expression was less anxious, pupils widely dilated, pulse full, quiet, and regular. During the day he had taken about a teacupful of rice pudding without much difficulty, and had drunk about a pint and a half of milk. He was so much improved at this time that a medical friend who saw him with me, and who had previously seen several cases of hydrophobia, entertained much doubt as to the genuineness of the disease. The patient was ordered an enema of chloral and bromide of potassium. It was given at 8.30 P.M. without difficulty, and he went to sleep between 11 and 12 P.M. After some broken sleep he finally woke at 5 A.M. on Feb. 4th, and suddenly manifested marked delusions, and became furiously maniacal. He had illusions of sight, and wanted to go through the window. He was a very powerful man, and it was with great difficulty that he could be restrained in bed. There were intervals of comparative calm, during which he could be reasoned with, but without effect. He expressed a wish not to hurt anyone, but during his furious delirium made determined efforts to bite the hands of those restraining him. The excitement was greater than anything I have witnessed in delirium tremens or in mania. He was treated by the hypodermic injection of morphia. At this time the noise of pouring out water gave him a convulsion. He was perspiring profusely, and the act of wiping the face with a handkerchief caused a spasm, as also did the draught of air caused by moving a towel near him. He said he was hungry, and called for meat. Some bread-and-butter was given him. He masticated it, but could not swallow it. He took water from a spoon, but refused a cup; the act of swallowing caused great excitement, and also spasms of the muscles of deglutition, lasting on the whole nearly a minute. In the intervals, though appearing rational, his statements were incorrect. For instance, he said he had been bitten only five weeks ago, and on the knee. The day before he had given a correct account. Talking of the dog or of the bite agitated him greatly. Among other illusions he saw a dog under the bed. He made most heart-rending appeals to those restraining him in bed, and taunted them with gloating over his misery. His death took place somewhat suddenly, apparently from

Digitized by Google

failure of the heart, twenty-eight hours after his admission into the hospital, and on the third day (little more than forty-eight hours) after difficulty of swallowing was first noticed. Half an hour before death he could swallow milk, but sputtered out some of it. From this time he was frothing at the mouth, hawking up and spitting saliva. Twenty minutes after death rigor mortis had commenced, and the temperature in the rectum was 108·8°. There had been but little spasm of the trunk or limbs during life, though much voluntary effort. No priapism or sexual excitement was detected.

The body was examined three hours after death. Rigor mortis was strongly marked, and post-mortem lividity of the dependent parts of the body was distinct. The spinal cord was removed first. The blood was dark and remarkably fluid. Nearly two pints of blood escaped during the removal of the cord. The brain was next removed. There was a moderate amount of subarachnoid effusion and congestion of the small vessels in the pia mater. The cortical grey matter of the brain and the adjacent white substance for about one-third of an inch had an evident pink flush, due to capillary congestion. There were no hæmorrhages visible to the naked eye. The larynx was examined, and the interior (especially the false cords) was dusky and much congested. The heart was dilated, but empty. The other organs appeared healthy. Parts of the medulla and of the cervical cord were at once placed in powdered boric acid and forwarded to the Brown Institute, and I hear, through the kindness of Mr. Victor Horsley, that rabbits inoculated with them died of typical rabies. Other parts were carefully hardened in bichromate of ammonia solution, but sections showed nothing beyond an unusual fulness of the vessels, many of which were thromboses, but this was probably a post-mortem effect. No cellular infiltration or unusual number of leucocytes could be found, either in the medulla near the origin of the vagus nor in the cervical cord, though carefully looked for. In two cases of rabies in the dog sections of the medulla and cord were examined, but nothing beyond marked fulness and dilatation of the vessels could be found. There was no cellular infiltration or distinct evidence of an inflammatory condition. The disease is apparently too little localised and too rapid in its progress for coarse tissue changes to be found.

In this case difficulty of swallowing was not a particularly prominent symptom, neither would changes in the medulla account for the furious maniacal excitement which with its sudden onset were the marked features of the case. During the early stage the symptoms were so slight, and their progress so little, that many considered the case one of nervous mimicry; while those who only saw him during the stage of delirium, taking into account the family history of insanity and the drinking habits of the patient, looked upon it as acute mania. The complete clinical picture, however, leaves no doubt, even if the inoculation experiments had not been performed. To sum up the special features of the case, the incubation period was long—four months and a quarter,—the early symptoms very slight and slow in progress, the outburst of delirium very sudden and its intensity unusually great, and the stage of excitement very short—seven hours.

As a contrast to the above, I may give a few details of the following case of tetanus which came under my care a few weeks later. It was at first supposed to be idiopathic tetanus—a disease of very doubtful existence—but a careful search resulted in the discovery of a wound. The history is as follows:—

On Monday, April 4th, J. W——, a labourer, aged twenty-eight years, noticed a sore on the sole of his foot, caused by a nail in his boot; the place had inflamed and "gathered," and was very painful. (On admission into the hospital this sore was completely healed, and not in any way painful.) On Tuesday he rested from work. On Wednesday he worked in the market all day. On Thursday morning he complained of his jaws feeling stiff. On Friday morning he walked a distance of two miles, and on reaching home burst into tears, saying he had fallen down four times. His jaws were now much more firmly closed, and he complained of great pain and a feeling of constriction round the lower part of the thorax, and of dizziness. He went to bed, and shortly after had an attack of opisthotonos. On Saturday his jaws were very firmly closed, and he was given twenty grains of chloral every two hours. In the evening the dose was increased to thirty grains. On Sunday he was much better. On Monday he was admitted into the hospital. He was very drowsy from the chloral, but when roused gave a clear account of his illness. He could open the mouth well, and during the day took three pints of milk without difficulty. The tonic spasm of the muscles closing the jaws had almost entirely passed off, neither was there any permanent arching of the back (from tonic spasm of the erector spinæ) or hardness of the abdomen. Possibly this was the effect of the large doses of chloral, which, however, had no effect upon the clonic spasms, which came on, without any apparent irritation from noise or draught, every two or three minutes. The spasm of the diaphragm, as evidenced by a sharp inspiration and pain at the epigastrium, was marked during each convulsion. The ease with which fluids could be taken without bringing on any spasm was remarkable. The patient was so drowsy on admission that the chloral was not resumed till evening, when he was ordered thirty grains every four hours, and he had the last dose at 5.45 A.M. on Tuesday. During the night he took only half a pint of beef-tea, as the difficulty of swallowing had increased. On Tuesday morning, at 6 A.M., it was not thought safe to give him any more chloral, as he was very drowsy; face inclining to be dusky; breathing noisy, 43 per minute; pulse 134 per minute; pupils contracted, but reacting to light. The general clonic spasms, which the previous evening had been from twenty to twenty-four in the hour, were still sixteen or eighteen—that is, coming on rather more frequently than once in four minutes. During the day he received nutrient and stimulant enemata, but the spasms continued at the rate of from four to fifteen in the hour, and he died at 7 P.M., the pulse failing some time before the respiration. Death took place on the sixth day after the commencement of the symptoms. An inspection of the body was made twelve hours afterwards. There was no undue fluidity of the blood, and no naked-eye change in any of the viscera. Portions of the spinal cord and of the posterior tibial nerve on the affected side were prepared for microscopic examination.

The points of interest are: the temporary improvement under the use of chloral; the cessation, to a very large extent, of the tonic spasm, and the facility in swallowing; the failure of the chloral, though pushed as far as was safe, to materially influence the general clonic convulsions, which remained severe till the last few hours of life; death from failure of the heart, rather than from spasm of the respiratory muscles during a convulsion, as is common.

A CASE OF HYSTERICAL SPASM SIMULATING TETANY.

BY F. FOORD CAIGER, M.D. LOND.

E. S——, a general servant, unmarried, was admitted into the Paddington Infirmary on Jan. 27th in a very prostrate condition. It was afterwards ascertained that she had always been delicate, but had had no serious illness until two years ago, when she was admitted into the Kensington Infirmary suffering from general weakness. Her teeth then became bad, and she had severe neuralgic pain in the face, and at the same time suffered from "cramps and fits." She stated that she then went out of her mind, and was removed to Leavesden Asylum, where she remained six weeks, and eventually went out to service. In her situation she was underfed, and at the same time was worked very hard. The catamenia have always been regular in time, but profuse. On the night of the 24th she was suddenly seized with cramps, beginning in the left hand and foot, extending up the limbs, and affecting the left side of the trunk, which gave her great pain. At the same time the left side of the face became rigid. This, in its severity, passed off in about half an hour, but continued more or less until she was brought to the infirmary three days later.

On admission the following notes were taken: Pale woman; very prostrate; surface cold; respiration hurried and shallow; complaining of painful cramp in the left arm, leg, and side. The fingers of the left hand are flexed, and adducted at the proximal joints and extended at the distal. The thumb is rigidly flexed into the palm, which is hollowed by contraction of the hypothenar muscles. The hand is thus bent into the form of a rigid cone. The wrist is partially flexed, and the forearm semiflexed and pronated, with some degree of rigid adduction of the shoulder joint. An analogous condition is present in the foot, the ankle

Digitized by Google

joint extended, and the leg straightened. The spasm likewise affects the muscles of the abdomen and the scapular group, the latter being very painful; and in the same manner the left pectoral and intercostal muscles. It is not obvious whether the diaphragm shares in the spasm. The left side of the face is rigidly fixed, and she is able to open her mouth but little, owing to contraction of the orbicularis oris and the muscles closing the jaw. There is partial but marked aphonia. All these spasms can be overcome by force slowly applied, but it gives her great pain. When the mouth is opened and she is told to protrude her tongue, it is done with difficulty, and it markedly deviates to the left. The left pupil is smaller than the right, but both react to light. There is blunted sensation over the whole of the left side of the body, including the tongue and conjunctivæ. Anæsthesia is complete in the foot, leg, hand, and forearm, but she complains of tingling in the finger tips. Patellar reflexes are natural and equal on the two sides. Subcutaneous œdema is present on the left side of the face, the extensor aspect of the left wrist and forearm, and the anterior tibial region of the same side. Temperature 99·2°; pulse 90; respiration 40, shallow and painful. Heart, lungs, and abdominal viscera natural. Bladder somewhat distended. Tongue coated. She complains of headache, shortness of breath, painful cramps, and inability to pass her urine.

On the following day it was noted that she had passed a restless night, but the muscular spasm had passed off, with the exception of that affecting the hand and foot, which still retained their characteristic form, and the spasm had persisted during sleep. She had passed urine, and was in comparative comfort, her respiration being quite unembarrassed. She was now able to open her mouth, and it was seen that all the teeth in the right upper jaw were carious, loose, and tender, with a painful spongy condition of the gums in their neighbourhood. The anæsthesia remained much the same. The left pupil was still smaller than the right, but the aphonia was only partial, and deglutition was less difficult. Temperature 99°; pulse 84.

For some days after this the patient's condition remained much the same. She was subject to paroxysmal aggravation of the spasms, recurring from four to six times in the twenty-four hours. In the intervals nothing beyond the contraction of the fingers, wrist, and foot was noticeable, and the continuance of the anæsthesia to a less degree. The paroxysms for the most part came on in the night, and some degree of spasm persisted during sleep.

On Jan. 30th I had the opportunity of witnessing the onset of one of these fits. It began suddenly, with a kind of snort. The hand, wrist, and foot then became more rigidly contracted, whence the tonic spasm quickly spread to the left side of the trunk, face, and neck. The left masseter was obviously contracted. Though quite conscious, she was unable to speak or move the left side of her body, and the breathing became stertorous and hampered through rigidity of the left side of the thorax. The pulse was accelerated; the pupils not dilated. After about fifteen minutes the attack passed off, and she returned to her usual condition. As soon as she was able to speak, she complained of great pain in the affected teeth. This pain, which was of a neuralgic character, spread all over the right side of her head. The scalp on the same side was very tender to the touch. She stated that these attacks were invariably preceded by aggravation of pain in the teeth and head. No effect was obtained by firm pressure applied to the ovarian region. The rigidity remaining constant in the hand and wrist, I tried the local application of chloroform, as recommended by Aran in Trousseau's Clinical Lectures. This was applied, sprinkled on a piece of lint, which was lightly bandaged round the wrist and forearm. In less than five minutes the spasm had completely relaxed, and for the first time since admission she was able to open her hand and move the fingers freely in all directions. The same plan, with like success, was tried with the foot, and at various times with different groups of muscles which were the seat of painful spasm, the result in each case being invariably the same. Muscular relaxation was also obtainable by plunging the hand and forearm into ice-cold water. This effect, however, was but transient. On no occasion could the spasm be reproduced by compression of the main bloodvessels of the limb.[1] The electric reactions were carefully tested. The result showed great diminution of electric irritability in the muscles of the affected side when tested with the constant current. The muscles of the right arm readily reacted to a current of ten Léclanché cells (KC), whereas twenty-six were necessary to obtain the faintest reaction on the left side. The qualitative reactions showed no abnormality. The cutaneous sensibility and muscular contractility to faradism were much diminished on the left side corresponding to the anæsthesia. It was only when the spasm was aggravated that it became painful, but at these times it caused her much distress.

On Feb. 4th, believing that her condition was in great measure referable to the painful and irritating state of her upper teeth, of which it seemed, as it were, the reflex expression, I caused her mouth to be thoroughly cleared of the offenders. Eight carious stumps in all were removed, including the central incisor on the right side, which was loose and intensely tender. At first the result seemed very satisfactory, for, with the exception of a slight attack shortly after the operation, she remained entirely free from spasm for three days, and the anæsthesia began to clear up in the extremities. The event, I am bound to confess, was very disappointing, for in ten days' time the spasms were as bad as ever. The aphonia, however, did not return. But from this time the nature of the affection underwent modification. The spasms began to show less marked resemblance to those of tetany, and the general features of the case became more distinctive of hysteria. The form of the hand became less typical, the fingers no longer taking the form of a cone with the thumb flexed across the palm. The wrist was often fixed in a state of extension, and the anæsthesia became more variable. Her mental condition, too, became less satisfactory; she evinced great irritability of temper, was emotional and disobedient, and took a morbid delight in annoying the other patients. At the same time she developed some transient delusions: saw faces looking at her through the window; imagined that the nurse had a spite against her, and declared that she saw the sister of the ward putting powders into the battery. Tenderness developed in the left ovarian region, and she had occasional auras. That her volitional control was much weakened was evinced both in her mental and physical actions. The power to overcome the contraction of one set of muscles was easily initiated by the application of the faradic current to the nerve supplying the opposing group, acting apparently as an adjuvant to her motor impulses. The spasms were always reduced by faradism, and this was used for a few minutes night and morning as a routine treatment, with the addition of a cold shower bath in the morning. By these means the frequency of the spasms was in great degree reduced and the anæsthesia lessened.

On the 25th the anæsthesia suddenly changed over to the right side and was complete, with the exception of the senses of sight and hearing. Occasional spasms occurred in the right arm and leg, and the symptoms became very variable. She became so troublesome and disobedient that on March 12th she was discharged from the infirmary.

Although from the beginning the hysterical element in the case was sufficiently obvious, yet certain of the symptoms were by no means characteristic of that complaint. I refer chiefly to the presence of fever, the distribution of the spasms, the marked affection of the muscles of the face and jaw, and the inequality of the pupils. On the other hand, the typical cone-shaped form taken by the hand and foot, the contraction of the wrist and ankle, which persisted in the intervals and during sleep, but were invariably reduced by the local application of chloroform or cold, their periodic and paroxysmal aggravation and diffusion, causing a condition of painful cramp, the rise of temperature, acceleration of pulse, and the presence of subcutaneous œdema in the parts most affected, bear a striking resemblance to those more severe forms of tetany so graphically described by Trousseau. A peculiar point was the unilateral distribution of the spasms. The connexion, too, with a diseased condition of teeth was interesting; and although the relief obtained by their extraction was but temporary, and therefore disappointing, yet the symptoms underwent modification from the

[1] I have since tried the local application of chloroform in this way in several cases of painful muscular spasm of varied origin, and in all with more or less success. In one of painful torticollis secondary to cervical caries the relief obtained was most marked. In another case of persistent spasm of the arm and leg of more than six months' standing, but whether of functional origin or due to organic lesion I am in doubt, probably the former, temporary remission of spasm lasting from half an hour to several hours could always be obtained by this means. I throw this out as a hint, as I think it, though obviously nothing new, worthy of more extended trial.

Digitized by Google

time of their removal, and did not again present the features so suggestive of tetany.

I regard this case as valuable, inasmuch as it tends to support the growing belief in the impossibility of drawing a hard-and-fast line between the so-called functional diseases of the nervous system. In this patient the neurotic diathesis was marked in every phase of her malady. Inheriting directly from her mother a legacy of nervous instability, what wonder that she should be prone to the development of nervous disorder, which found expression both in her psychical and physical processes. Whether the case be regarded as one purely distinctive of hysteria, or whether it be looked upon as one of hysteria in which a group of symptoms conforming to the type of tetany were superadded as a consequence of some other morbid process, is, I think, a matter of speculation.

Lindfield, Sussex.

TWO CASES OF CYSTITIS, WITH UNUSUAL COMPLICATIONS.

BY GILBERT BARLING, B.S., F.R.C.S.,
ASSISTANT SURGEON TO THE GENERAL HOSPITAL, BIRMINGHAM.

CASE 1.—A gentleman, aged twenty-seven, consulted me in January last for frequent and painful micturition, which had been troubling him for a few days. My first note of him, made January 8th, was: Micturition twelve times in the last twenty-four hours; necessity for immediate expulsion when the demand arose; pain in the perineum and at the end of the penis after micturition; temperature practically normal. Urine faintly alkaline, but not ammoniacal; sp. gr. 1018; a slight deposit of pus and mucus; *albumen nearly one-half of a column.* Microscopic examination showed pus and a few blood corpuscles, but *no casts*, after a most careful search. There was no œdema or headache, and except for the local trouble the patient felt little the matter with him. With complete rest in bed and milk diet he rapidly improved, and on Jan. 14th the micturition was less frequent and painful; the urine contained more pus, but no blood, and the albumen was only one-fourth of a column, and there were still no casts to be found. He then commenced to take small doses of copaiba.—Jan. 17th: The albumen was reduced to one-sixteenth of a column, and he was in all respects better.—18th: Aching pain in the right knee joint, which was rather hot and swollen.—20th: Right knee full of fluid; slightly painful; no inflammatory blush over it. Left ankle slightly swollen. No fever; no sweating. Pulse 76. Joints fixed on a McIntyre's splint and covered with evaporating lotion.—22nd: Urine almost free from pus; albumen one-eighth of a column. Micturition almost as in health. Joints much the same. Tongue furred. Anorexia. Pulse 80; temperature 99°.—25th: Right knee still very tense; left ankle better, but left knee distended with fluid, and similar to the condition of the right on Jan. 20th. No sweating or fever. Tongue very furred.—28th: Pus and albumen have disappeared from urine. Right knee and left ankle diminishing in size; left knee very tense.—31st: Phalangeal joint of left great toe red, swollen, and tender; other joints much better, and now treated with mild counter-irritation. Tongue still very furred.—Feb. 4th: All the joints better. Tongue cleaner. Desire for food returning.—20th: The swelling has disappeared from all the joints except the left ankle. The tongue is clean, and the urine healthy. Soon after this the patient went to the seaside, and resumed his business at the end of a month. There is no doubt that the attack was produced by exposure to the extreme cold at the end of December, 1886.

CASE 2.—H——, a labourer, aged forty, was in the General Hospital under my care in September, 1885, suffering from cystitis. His trouble commenced six months previously, when he was under treatment in a cottage hospital for fracture of the femur. Owing to his recumbent position he had difficulty in micturating, which ended in retention ten days after his admission. The bladder was emptied once with the catheter, and soon after he noticed blood in his urine, which became thick, and later contained pieces of grit. The hæmaturia continued until he came to the General Hospital, when he also complained of frequent micturition, pain in the perineum, and especially of pain in the glans penis after micturition. On sounding, patches of calculous matter were detected, some of them appearing to be fixed on the surface of the bladder. Rectal examination revealed no thickening of the base of the bladder. The pathologist, Dr. Bull, reported on the urine as follows: "Colour yellowish-red; alkaline; ammoniacal: specific gravity 1015; *albumen half a column.* Microscopic examination: Triple phosphates, blood, pus, vesical epithelium, and a few doubtful granular casts." After a week's rest in bed, with careful emptying of bladder and washing out with boracic acid solution, the condition of the urine had improved somewhat, the albumen had diminished to one-third, and prolonged search failed to find any casts; but the patient was much worn by pain and broken rest, so I performed the "Boutonnière" on Sept. 29th, partly to evacuate the small concretions that the sound detected, and partly for the purpose of draining the bladder. A few grains of free calculous matter were removed, and some adherent patches were scraped off; but the most important condition found was a patch of ulceration about two inches in diameter on the trigone and its neighbourhood. The ulcer was of considerable depth, and surrounded by numerous warty elevations coated with calculous matter, suggesting to my mind that I had to deal with a malignant growth; I therefore removed some of the warty parts for further examination, and secured a drainage tube in the bladder. Microscopic examination of the warts showed nothing but granulation tissue in various stages of development. On Oct. 5th the tube was removed, as it was beginning to annoy the patient, who otherwise made an excellent recovery, interrupted only by an attack of epididymitis on the eighth day. On Oct. 22nd some urine passed by the urethra was examined; it was slightly ammoniacal, and contained a thick cloud of albumen, a little pus and blood, and some phosphatic crystals. A week later there were only a few pus-cells, and a trace of albumen in the urine, and the patient was discharged on Nov. 7th, reporting himself some weeks later as being perfectly well.

Remarks.—I have described these two cases together, as they had in common what is, I believe, a very unusual condition in cystitis uncomplicated with nephritis—viz., severe albuminuria, which I presume was dependent upon a large serous exudation from the blood-vessels of the mucous membrane of the bladder, and perhaps of the upper urinary tract, or, in the second case, from the ulcerated bladder surface. The joint complication in the first case did not closely resemble either urethral arthritis or acute rheumatism, being of a much milder type than is generally noticed in the former, and without the severe pain, sweating, and fever of the latter. The rapid and complete recovery after drainage in the second case was most satisfactory.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON THE LOCAL TREATMENT OF PSORIASIS.

BY JOHN KENT SPENDER, M.D. LOND.,
PHYSICIAN TO THE ROYAL MINERAL WATER HOSPITAL, BATH.

I IMAGINE that dermatologists are coming to the conclusion that the more circumscribed a skin disease is the more is it a purely local affair, requiring to be treated mainly with outside methods. If a person has, for instance, two or three dull-red mahogany-looking patches of psoriasis, now and then perhaps somewhat inflamed, but always so abrupt in margin that a pen or pencil line can be drawn round them, we should think first and almost solely of remedies applied to the visible disease, whatever may seem fitting to be done as internal confederates and helps.

Now, if there be any disease for which thermal bathing is almost always successful, it is the common *psoriasis diffusa* when treated with the Bath mineral waters. Adults and children come who are "white as snow and scaly as hoar frost"; and without taking any drugs (usually so called) they often leave Bath in less than six weeks (unless the disease be chronic and very defiant) with the skin physio-

Digitized by Google

logically sound and texturally pure. Nothing within the range of what is termed balneo-therapeutics is more trustworthy than this. A contrast to this generalised condition of things was lately seen in an Irish gentleman sent to me by Mr. Malcolm Morris, who had on the skin of the pubes a symmetrical dark-red patch, absolutely dry and very irritable. The patient left Bath without much benefit; the lenient influence of a hot alkaline water did not penetrate far enough to alter the deep pigmentation of the dermal structures, although the hypertrophy of superficial layers of cuticle seemed to be modified and "tamed down." Shortly after this Mr. Morris told me that he quickly cured his patient's malady by a combination of chrysophanic acid and lanoline.

One of the objects of this short paper is to give my experience of Auspitz's method, which consists in creating an artificial cuticle or film with certain substances dissolved in chloroform or gutta-percha.[1] This cuticle is made by dissolving one part of purified gutta-percha in ten parts of chloroform, which forms an excellent medium for fixing the application, as it adheres firmly and without alteration for several days. It is thin, chemically neutral, and does not cause tension or pain. Dr. Payne has further illustrated the subject in the last number but one of the St. Thomas's Hospital Reports. He proposes a solution of chrysarobin (20 grains) in a fluid ounce of liquor gutta-percha. This is to be painted with a brush on the affected places (from which the scales have been removed as much as possible by soft soap) once or twice a day, so as to form a perpetual film. The action is more rapid, and there is no staining of the clothes. The principle is capable of variation in detail, but Dr. Payne claims for the plan that it is specially neat and cleanly for the purposes of private practice. Chrysarobin thus applied, adds Dr. Payne, supersedes all other remedies. Perhaps this last assertion is too absolute, as there are not a few people who instinctively dislike any varnish which *seals up* the skin and shuts in the natural secretion of the smallest cutaneous area. Otherwise, I can heartily commend Dr. Payne's modification of Auspitz's method used within narrow limits. The principle has already been tested in the treatment of eczema. Under the protective guardianship of a gelatine enamel, irritation subsides, and a healthy epidermis is developed within a few days. Here everything depends upon the temporary exclusion of air, with all its impurities of dust and tribes of germs.

INJURY OF THE HEAD, IMMEDIATELY FOLLOWED BY SYMPTOMS OF COMPRESSION; TREPHINING; RECOVERY.

BY GEO. HERBERT WILLIAMS, M.R.C.S. ENG., L.R.C.P. EDIN., LATE HOUSE-SURGEON, ROYAL INFIRMARY, MANCHESTER.

ON May 3rd, 1887, about 10 P.M., I was called to see A. W——, a lad of nine, with the following history:—Two hours previously, the child had tripped at play and fallen on the left side of his head. He was, however, able to run home, where, complaining of pain, dimness of vision, and sickness, he was enjoined to lie down and rest.

On my arrival, two hours later, I found the patient lying on his back, and my attention was first directed to a contusion over the left temporal bone about the size of a Tangerine orange. No fracture could be felt at the seat of injury. The left side of the body was affected with clonic convulsions; the right hemiplegic; pupils widely dilated; conjunctivæ insensible to touch, and breathing stertorous. After a consultation it was decided at once to trephine over the seat of injury, as the only prospect of relief from imminent death. The coma was so profound that no anæsthetic was necessary. After carefully incising the periosteum, and turning it back, a circle of bone was removed, as near the seat of injury as possible, when a considerable amount of venous blood was immediately poured out. The finger was then introduced, and swept round the inside of the skull, but as no clot or spiculum of bone could be found, and the symptoms being still unrelieved, I nicked the dura mater, and incised it the length of the trephine wound, when the convulsions and hemiplegia almost simultaneously disappeared. The soft parts were then replaced, and the skin flaps brought together with a few points of suture, a drainage-tube being introduced, the length of the wound. The little patient was then removed to bed, and slept soundly for about four hours.

On my next visit—ten hours after the operation—I found him sitting up in bed calling lustily for breakfast. From this date the recovery was rapid and satisfactory. On the twentieth day the wound was quite healed, with a fair deposit of new bone, and the boy was out at play.

Remarks.—I must admit that, as there was no fracture or depression, I expected to find a clot on the dura mater, which, as already stated, was not the case, and yet one can scarcely think that the venous blood that followed the removal of the circle of bone was sufficient in itself to relieve the right hemiplegia. It is just possible the left convulsions may have been caused by *contrecoup*; but whatever the true pathology of this interesting case may be, I feel convinced in my own mind that the well-marked relief was brought about by incising the dura mater, and thus relieving the intra-cranial pressure.

Lockwood, Huddersfield.

POISONING BY LABURNUM SEEDS.

BY SYDNEY H. A. STEPHENSON, M.B. EDIN.

ON March 23rd, 1887, a number of girls, who were convalescent from ophthalmia, went into their play-yard after their dinner at 12.30 P.M., where they picked up and ate some laburnum seeds. The seeds had been blown over into the yard from some neighbouring laburnum trees. The nurse in charge, on going into the yard at about 3 P.M., found a girl vomiting, and in the course of a few minutes five other girls commenced to vomit; they were all very white, complained of pain in their heads, and were shivering. The nurse could ascertain no cause for their sudden and simultaneous illness, which she thought might be due to something they had eaten at dinner, and which had disagreed with them. When I saw the children at 3.30 P.M. they had been put to bed; they all denied having eaten anything in the play-yard, and it was with some difficulty that I elicited the real facts from the eldest of them. Their individual states were as follows:—

CASE 1.—Age twelve years. Had eaten two seeds, and had vomited four times. This patient was lying flat on her back in bed, shivering violently; her face was shrunken and her lips were very white. She answered questions in a whisper, and with difficulty; said that she had pain in her head. Her pupils were equally dilated, acting both to light and to accommodation. Pulse feeble, 124 per minute; temperature in axilla 98°.

CASE 2.—Age nine years. Had eaten four seeds, and had vomited three times. General state similar to the first case. Pupils active and dilated. Pulse 132 per minute; temperature 97·4°.

CASE 3.—Age six years. Had eaten one seed, and had vomited once. Was pale and shivering. Pupils dilated. Pulse 100 per minute; temperature 97·6°.

CASE 4.—Age eight years. Had eaten three seeds, and had vomited twice. Complained of great pain in her head. Pupils dilated. Pulse 106 per minute; temperature 97°.

CASE 5.—Age four years. Had eaten one seed, and had vomited three times. Pupils dilated. Had headache. Pulse 120 per minute; temperature 97·4°.

CASE 6.—Age five years. Had eaten one seed, and had vomited five or six times. Very pale, and shivering a great deal. Pupils dilated. Pulse 136 per minute; temperature 97·2°.

Two other children had eaten some (two or three) seeds. Neither of them had vomited; but both were very pale, had dilated pupils, rapid pulses, and temperatures below 98°. Later in the day, at 5 P.M., about two hours and a half after the time the rest of the children are supposed to have eaten the seeds, two other girls commenced to vomit, complained of headache, and had dilated pupils and rapid pulses. In all the cases the vomited matters consisted of particles of food mixed with brownish-coloured mucus, which in the first case was slightly tinged with blood. At 8 o'clock in the evening the sixth case was covered from head to foot with an eruption of large red patches, much resembling scarlatina. This had quite disappeared by 10 A.M. on the following morning. All the patients were well on March 25th. The treatment adopted was to inject ether hypodermically, and then to give large draughts of tepid

Digitized by Google

salt water, which in every case produced copious emesis. At night the patients were given an ordinary purgative. The evidence as to the number of seeds they had each eaten rests upon their own statements, corroborated in most cases by two of the elder girls, who had given the seeds to the younger children.

I do not find many cases of poisoning on such a large scale by laburnum seeds recorded. Bonney, in THE LANCET for 1841, records that eleven boys were poisoned at Brentford by eating from one to five seeds apiece. One case had somewhat serious symptoms, but all recovered. The general mildness of the symptoms was attributed to the fact that they took the poison immediately after dinner. In 1856 twelve children were poisoned by the seeds at Otley, and all recovered. Dr. Hair, in the *British and Foreign Medico-Chirurgical Review* for 1869, gives particulars of a similar set of cases which occurred at Carlisle. Mr. Boyd Joll, in the *British Medical Journal* for 1879, records cases amongst an unspecified number of children, whose ages varied between six and fourteen years, and who all recovered. The symptoms in the cases I record were fairly uniform, and very similar to those given by the above-mentioned authors. All my ten cases had active dilated pupils, rapid pulses, headache, blanched features, and temperatures of 98° or below; and eight out of the ten had vomited without the help of emetics. No purging, abdominal pain, or tetanic convulsions occurred in any of the cases.

Lambeth Old School, West Norwood.

DYSPNŒA AND ASTHMA.

By BENJAMIN WALKER, L.R.C.P. ED.

THE clinical lecture on "Dyspnœa, especially on the Dyspnœa of Asthma and Bronchitis, and the effects of the Nitrites upon it," by Dr. Fraser, in THE LANCET of July 9th, is a most valuable contribution to the pathogeny of this symptom. He has logically and convincingly proved that it is due to spasm of the involuntary muscular fibres, "that stenosis of the bronchi due to spasmodic contraction of the bronchial muscles is a frequent cause of the dyspnœa of ordinary bronchitis." And "as nitrites lessen the contraction of non-striped muscle, it appears to follow that the râles which accompany the dyspnœa of asthma are produced by spasmodic contractions of the bronchial muscles, that the dyspnœa is mainly the result of spasmodic constriction of the bronchial tubes, and that therefore the old doctrine which attributes the asthmatic paroxysm to spasm of the bronchi is in all probability the correct doctrine."

For the last six years I have successfully treated the dyspnœa of asthma and bronchitis on the above theory of its causation, though not by the remedies of Dr. Fraser. The treatment by the nitrites advocated by him does not seem from the cases adduced to produce very stable and permanent results, though the symptom is momentarily relieved. Thus in the first case adduced complete relief was afforded after the inhalation of nitrite of amyl for a minute or two, but in five or six minutes "both the râles and dyspnœa were present in their original abundance and severity," and the same result followed two more applications of the same remedy. The two cases used as illustrations before the class were also at once relieved—one by the nitrite of amyl and the other by nitro-glycerine, but we are not informed whether there was a recurrence of the dyspnœa shortly after; and Dr. Fraser goes on to say that he has "not obtained any facts which would justify the preference of any one of the nitrites."

The object of this communication is to call attention to the action of hyoscyamine in this affection, and indeed in the treatment of spasm of involuntary muscular fibre, wherever existent—whether in the bronchi or hollow viscera (stomach, bowels, bladder). Given in the dose of half a milligramme ($\frac{1}{130}$ gr.), according to the urgency of the case, every half-hour or hour, until the spasm disappears, it is rare for the patient to be unrelieved after two or three doses; in cases of great urgency the first dose may be in the form of a hypodermic injection for quicker absorption. When relief is afforded, it may be given less frequently (two or three times a day), and gradually left off. I have never been disappointed with its action; it relieves the spasm promptly and efficiently, and the patient has no dread of an immediate recurrence of the dyspnœa. A young woman who is subject to occasional attacks of asthma came to me on June 7th and was quite relieved in twenty-four hours. She did not, however, continue the remedy at longer intervals for some days, as she should have done, and so had a recurrence three weeks later. She was, however, quite cured after four or five days' treatment, and has since remained well. Her previous attacks occurred in March, 1887, May, 1886, and December, 1885, when the same treatment was equally, and as quickly, successful; so that the intervals of immunity vary from three to ten months. I usually give with the hyoscyamine small doses of strychnine (the arseniate or sulphate), in half-milligramme doses, as a tonic, and to counteract the tendency to adynamy.

In spasm of the stomach or bowels, in dysentery, in strangulated hernia, and in retention of urine due to spasm of neck of bladder, hyoscyamine in small and frequent doses is invaluable, and will be the first remedy thought of by anyone who once gives it a trial in these affections. I would refer the reader to a paper on "Advanced Pharmacy" in THE LANCET of Dec. 10th, 1881, in which this method of treatment by the alkaloids in small and repeated doses is advocated in preference to the crude preparations of the Pharmacopœia.

CHARING-CROSS HOSPITAL.

A CASE OF ACUTE ULCERATIVE ENDOCARDITIS; DEATH IN EIGHT DAYS; NECROPSY; REMARKS.

(Under the care of Dr. JULIUS POLLOCK.)

THIS would appear to be one of those examples of malignant endocarditis in which no cause for the development of the disease can be found, there being an absence of history regarding those affections to which endocarditis is attributed. In 209 cases of this disease, collected by Dr. Osler,[1] no cause could be assigned in forty-five, and many of these were of a most malignant type. The primary disease was limited entirely to the aortic valves, and, although it was sufficiently extensive to produce most acute symptoms, there was no bruit or other evidence to permit of its localisation during life.

J. M——, a male, aged twenty-seven, was admitted under the care of Dr. Pollock on May 16th, 1887, complaining of excessive dyspnœa without any exertion, slight cough, but no expectoration. These symptoms had lasted about six weeks, but had lately increased in severity, and he sought admission to the hospital. There was no history of rheumatism or syphilis.

On admission, the patient was pale, and his skin had a yellowish tinge; eyes rather sunken; some working of the alæ nasi; cough, with slight expectoration of a darkish-coloured sputum. Lungs: No dulness on percussion; expansion not diminished; no râles; no bronchial breathing. Heart: No hypertrophy; percussion dulness normal; first sound at apex rough and reduplicated; aortic sounds normal. Urine: Sp. gr. 1020; no blood or albumen. Ordered fifteen grains of citrate of potash in an ounce of water every four hours.

May 17th.—Dyspnœa more marked, and expectoration more profuse. Temperature 99·4° at 10 A.M.; 103° at 6 P.M. Pulse 120; respiration 52.

19th.—Dyspnœa very great; sleepless. Temperature 98·4° at 10 A.M.; 101·8° at 10 P.M. Ordered ten minims of tincture of digitalis to each dose of the mixture, and four ounces of brandy.

21st.—Bowels much relaxed. Temperature 99° at 10 A.M.; 102° at 10 P.M. Pulse 124; respiration 52. Ordered ether and ammonia mixture, with ten minims of tincture of digitalis.

22nd.—Diarrhœa profuse. Temperature 97·6° at 10 A.M.; 103° at 6 P.M. Pulse 124; respiration 52. Dyspnœa extreme. Brandy increased to six ounces.

[1] THE LANCET, vol. i. 1885, p. 504.

Digitized by Google

23rd.—Weaker. Ordered two grains of sulphate of quinine every four hours. Brandy increased to eight ounces.

On the 24th he died.

Necropsy.—Heart: Excess of fluid in the pericardium; mitral valve normal. Attached to the ventricular surface of the anterior cusp of the aortic valve was a mass of coagulated fibrin, an inch in length and five-eighths of an inch in breadth at its widest part. On the adjoining surface of the next valve to the left was a clean-cut hole, about one-fifth of an inch in diameter, with slightly thickened edges. Before opening the aorta, the valves were tested and found to act efficiently. The remaining cusp of the aortic valve was thickened at its free edge, and had a superficial ulcer at its posterior part. The other organs were healthy, and no infarcts were found.

Remarks by Dr. POLLOCK.—This is a very acute case. Ulcerative endocarditis with pyæmic symptoms appears to have several phases. Sometimes it closely resembles typhoid fever, and is often accompanied by diarrhœa. In the present case the earlier phenomena were rather like those of pneumonia, but in a few days the nature of the disease became apparent. It is interesting to note that throughout there was no cardiac bruit, notwithstanding the diseased state of the aortic valve. The absence of bruit was no doubt due to the fact that the aortic valves were competent. There appears to be a sort of hurried and distressed action of the heart in these cases of acute ulcerative endocarditis, difficult to describe, but very suggestive, and which may be readily recognised.

WEST KENT GENERAL HOSPITAL.

STRICTURE OF ŒSOPHAGUS; GASTROSTOMY; DEATH FOUR MONTHS AFTER THE OPERATION; NECROPSY; REMARKS.

(Under the care of Dr. HOAR and Mr. KNOWLES.)

FOR the following notes we are indebted to Mr. George Wale, house surgeon.

James K——, aged sixty, attended as an out-patient on Sept. 15th, 1886, and complained of difficulty in swallowing. He said he had suffered for years from indigestion, flatulence, anorexia, occasional vomiting of food, and winter cough. He first noticed difficulty in swallowing solid food about two years previously. This gradually increased, and he could only swallow soft food and fluids.

The patient was a spare man, with an anxious expression. On examining his chest nothing abnormal was detected, but on auscultating over the cervical vertebræ during deglutition, the passage of fluid was heard delayed. There was no specific history; no history of traumatic origin; family history good. On passing a medium-sized œsophageal bougie, it was arrested at the cardiac end of the stomach, and felt to be gripped. He attended until Oct. 9th. The diagnosis was malignant disease of the œsophagus. Ordered five grains of iodide of potassium, fifteen minims of liquor morphiæ mur. in half an ounce of water, three times a day.

On Oct. 18th the man went to St. Thomas's Hospital, and was admitted. While there an œsophageal tube (size of No. 7 catheter) was passed, through which he says he was fed with a mixture of milk, beef-tea, and eggs, the tube being removed, cleaned, and reinserted every four days. He left, contrary to their advice, on Nov. 5th.

Nov. 6th.—Admitted into the West Kent Hospital wearing an œsophageal tube. Looks thinner (weight 7st. 13½ lb.). Frequent cough, with frothy expectoration; a good deal of wheezing over both lungs. Swallows fluids fairly well with tube in throat. Is fed through tube four times a day with milk, beef-tea, and eggs, strained through muslin.

16th.—As it was thought that the tube increased the bronchial irritation, and it was found necessary to change it more frequently than every fourth day owing to its becoming plugged with mucus, and as the difficulty of its reinsertion increased each time, and the patient was losing flesh (weight 7 st. 11 lb.), it was decided to perform gastrostomy. The incision was made, about three inches in length, in the usual position, the subperitoneal fascia exposed, and the peritoneum divided upon a director. A portion of the transverse colon which presented, was drawn down, and the stomach then brought into view. This was pinched up with the fingers and thumb of the left hand, and a small portion withdrawn through the wound and transfixed with two hare-lip pins, one supporting the portion transfixed at the upper angle of the wound and the other at the lower angle. One or two wire sutures were used to bring the ends of the incision into apposition, as it was too long, and the wound covered with protective and carbolised wool.

17th.—Pulse 100; temperature 101°. Tongue moist. Passed fairly good night. Is fed by enemata every four hours. Is still wearing œsophageal tube, although plugged. Swallows fluids more freely than before the operation, but the attempt to do so gives rise to dragging pain at the wound.

18th.—Some low delirium at night. Pulse 100; temperature 100°. Tongue moist. Cough troublesome. Fifteen minims of liquor morphiæ hyd. and twenty grains of bromide of potassium in half an ounce of water given three times daily.

19th.—Delirious at night. Plugged tube withdrawn and found to be kinked. Swallows fluids fairly well. Pulse 90; temperature 100°.

21st.—Pulse 88; temperature 99°. Tongue coated, moist. Wound looks well; adhesions formed all round. A tenotomy knife was passed into the stomach wall, and a small piece of drainage tubing inserted, the end being threaded and strapped to the abdominal wall. One hare-lip pin withdrawn.

23rd.—Pulse 94; temperature 99°. The other hare-lip pin withdrawn. Considerable oozing through and around tube. Drainage tube changed for a piece of green elastic catheter and plugged. Swallows with greater difficulty. Looks much thinner. A good deal of cough and bronchitic expectoration.

25th.—Some oozing still from wound. Stomach well united to abdominal wall, but a sulcus left between the two at the lower end of the incision. A small-sized indiarubber tracheotomy tube, plugged, and strapped to abdominal wall, used to replace the catheter after a three-ounce mixture of milk and beef-tea had been injected.

26th.—No oozing. Three ounces of food injected with syringe twice a day.

27th.—No oozing. Six ounces of food injected twice a day. Wound contracting; sulcus filling up with granulations. Some of enemas returned.

29th.—No oozing. Ten ounces of food injected three times a day. Can only swallow a few teaspoonfuls of hot fluid per diem. Was given some meat lozenges to relieve dryness of mouth. Cough less troublesome. Sibilant rhonchi and râles over both bases.

Dec. 4th.—Twelve ounces of food injected three times a day. Enemas stopped. Got up on to a couch.

9th.—Twelve ounces of food injected four times a day. Went out into the garden. Weight 7 st. 3 lb.

26th.—Weight 7 st. 11 lb. Cough troublesome, especially at night. He gets out every day, and can do light work (sweeping, &c.). The patient is taught to feed himself by means of an irrigator and long indiarubber tube. There is no oozing. The plugged tracheotomy tube is kept in position by a firm abdominal belt.

Jan. 12th, 1887.—Weight 7 st. 12½ lb.

Feb. 12th.—Weight 7 st. 10 lb.

March 4th.—Weight 7 st. 4 lb. Patient evidently losing ground; face looks more pinched; cough more constant; pulse weaker; marked emaciation.

15th.—Died, four months after the operation.

Necropsy.—Body very emaciated. The œsophagus and stomach were removed entire, with that portion of integument attached to margin of wound. The stricture was not at the cardiac orifice, its lower margin being an inch and a half above, and it extended upwards for two inches and a half. Its upper orifice was a mere chink, barely admitting a probe; its canal very sinuous, and some ulceration was present in its posterior wall. It was a well-marked scirrhous growth, and it involved the thoracic duct. There was some dilatation of the œsophagus above the stricture. The opening into the stomach was situated midway between the greater and lesser curvature, four inches from the pylorus, and three inches and a half from the cardiac orifices. The integument was firmly and evenly united to the stomach, the adhesions being above a quarter of an inch thick. Between the opening and the pylorus the stomach walls had undergone considerable hypertrophy. Lungs: There were a few pleuritic adhesions, and the base of the left lung was in a condition of red hepatisation. The other organs were normal.

Remarks by Mr. KNOWLES.—The method of fixing the stomach in this case—viz., by hare-lip pins—is that proposed and adopted by Mr. Bryce Barrow in a case operated on by

Digitized by Google

him at the West London Hospital. The advantages of this procedure are its easy application and its means of securely fixing the stomach, which in this instance was very desirable on account of the very troublesome cough. The amount of adhesion between the stomach and the abdominal parietes was ample and firm, as shown by the post-mortem examination.

WOLVERHAMPTON AND STAFFORDSHIRE INFIRMARY.

EPITHELIOMA OF PENIS AND SCROTUM, WITH ENLARGED INGUINAL GLANDS; COMPLETE REMOVAL OF EXTERNAL GENITALS, FOLLOWED BY RECOVERY AND AN APPARENT CURE.

(Under the care of Mr. VINCENT JACKSON.)

J. T——, aged fifty-one, single, was admitted in May, 1886. He had never had gonorrhœa or syphilis. There was no family history of cancer. Fourteen days ago he landed in Liverpool from America, and, having tramped to the Cannock Workhouse, was from there sent to the hospital. The man is tall, pale-faced, and a gardener by occupation. Two years since he noticed a small warty growth on the under surface of the penis. This gradually extended in all directions, until the whole of the penis and the greater part of the scrotum were involved. The discharge was free and most offensive in odour. Pain was not complained of. From childhood the prepuce has never been retracted. The chain of glands in each groin running parallel with Poupart's ligament is enlarged, but the glands are not tender, and are freely movable in all directions on pressure. The examination of the urine indicated no abnormality.

On June 3rd, ether having been given, Thiersch's operation was performed, the testes, as well as the penis and scrotum, being removed. Before the necessary dissection was commenced, the corpus spongiosum and urethra were exposed, divided across, and freed from their connexions as far back as was necessary, to permit the urethra to be stitched to the lower angle of the wound without the slightest traction. During the operation the bleeding was free, and required to be arrested by ligatures and forci-pressure forceps. The lateral portions of the scrotum which had been left were united along their edges by points of gut suture. The whole having been dusted over with iodoform, covered with cotton wool, and fixed by a binder, the patient was removed to bed.

In the after progress of the case there was nothing of importance to report; a portion of the flaps as well as of the deeper tissues sloughed, but the wound soon cleaned and the healing process was quickly concluded. As the enlarged inguinal glands were, if anything, a little smaller than when admitted, the patient was discharged in July without their removal. In May, 1887, the patient visited the hospital, and in appearance he seemed to be in perfect health. There was no return of the disease, and the enlarged inguinal glands had disappeared. The perineal urethral orifice was perfectly patent, the mucous membrane being slightly prolapsed.

Remarks by Mr. JACKSON.—This case is published as a contribution to the surgery of this particular operation, and as distinct evidence that it is not only curative but permanently so. No doubt cases are observed which possibly are considered, on account of the depth and extensive area of the malignant ulceration, to be beyond the reach of prudent surgery. The case reported was, I consider, approaching the border line of those cases which may be removed and those which no experienced surgeon would feel justified in jeopardising the life of his patient by attempting, not a forlorn hope, but a foregone conclusion. I have not witnessed a more extensive case of epitheliomatous ulceration of the male external genitals than the present one, and in attempting its entire removal I felt that the operation to be permanently successful must be as radical as it was possible to make it. The encircling incisions were made as wide of the disease as possible, and after the testes had been exposed, enucleated, and removed, the urethra was cut across, and, with the corpus spongiosum, was dissected back until pendent; it occupied the lower angle of the wound. In removing the body of the penis, and in separating by a process of tearing and scraping the crura from their bony attachments I was not prepared for the rather free hæmorrhage which had to be assuaged, as previous writers in reporting cases of Thiersch's operation had stated that the bleeding was slight and easily controlled. The recovery of the patient after this severe operation may be considered satisfactory, and the process of healing rapid. There cannot be the slightest question that the operation removed a most loathsome and destructive disease, and by so doing restored to activity, comfort, and a renewed life a man who would quickly have ended his days worn out by the consequences of so terrible an infliction.

Reviews and Notices of Books.

The Diseases of the Ear and their Treatment. By ARTHUR HARTMANN, M.D. Berlin. Translated from the Third German Edition, by JAMES ERSKINE, M.A., M.B. Glas. Edinburgh: Young J. Pentland. 1887.

Practitioner's Handbook of Diseases of the Ear and Naso-Pharynx. Third Edition of the Aural Surgery. By H. MACNAUGHTON JONES, M.D., M.Ch.

DR. HARTMANN'S work will be found very useful, containing just the kind of information that is requisite for the diagnosis and treatment of diseases of the ear. It does not profess to be a book for specialists. After a few pages which are devoted to a brief historical retrospect, the book may be said to commence with a description of the different methods of examination, and in this chapter the testing of the hearing by the tuning-fork is described in a more thorough and complete manner than we are accustomed to see in any of our English text-books. A short chapter is devoted to some special symptoms, and another to general therapeutics; and then at page 76, in a book of 250 pages, the diseases of the auricle and external meatus are described, the middle and internal ear following in their natural order. Each chapter opens with a brief anatomical description of the part involved in the diseases about to be described, which serves to refresh the memory of those who have not had recent opportunities of working at the subject. The account given of the various diseases and the treatment that should be adopted is, as a general rule, admirable, especially where local treatment is required. A little more stress might, we think, be laid upon the value of scraping out granulations and old caseous products from the middle ear with a sharp spoon under an anæsthetic. The author, on the other hand, advocates the use of a special metallic tube connected by rubber with a syringe. If the former be intelligently and skilfully performed, it is of great assistance to the latter operation, and should be accompanied by no greater risk than the forcible injection of fluids into the tympanic cavity. The old intra-tympanic injections through the Eustachian tube for chronic dry catarrh of the middle ear are still apparently recommended. We wish that the author had had the boldness to say at once how useless it is as a curative measure for this variety of deafness, where no secretion exists. There is very little said about cerebral abscess dependent upon disease of the ear; and absolutely nothing worth reading as to its treatment. At the present day we should expect to find in a book so good as this some expression of opinion as to when and under what circumstances the skull should be trephined; and the exact site of operation in different cases ought to have been discussed. The book, however, taken as a whole, appears to us to be the best in the English language for the class of readers for whom it is intended—namely, those who have not time to read such works as those of Politzer, Gruber, and Tröltsch. The translation, with the exception of a very few German sentences which have not received quite enough alteration in construction, leaves nothing to be desired.

The previous editions of Dr. Macnaughton Jones's book have been favourably noticed in THE LANCET, and the new one has been made more useful to its readers by the addition of a few coloured plates, taken from Dr. Jones's Aural Atlas.

Digitized by Google

of the more common diseases affecting the membrana tympani. Out of a book of 160 pages the first eighty are devoted to etiology, methods of examination, and general therapeutics. Much space is here given to the display of surgical instruments, which may be found in any surgical instrument maker's catalogue. At the same time it is only fair to say that the directions are good and to the point. At page 84 the reader finds that at last he may commence to study the diseases of the external ear, but through this and subsequent chapters he has constantly to refer back to much that has been previously said. This is troublesome, and in some instances unnecessary, but it is obviously difficult to avoid. Dr. Jones includes the diseases of the naso-pharynx in his book, and is thus able to describe one of the common causes of deafness in children—namely, adenoid vegetations. The clinical account of this condition which he gives is good, and would enable anyone to recognise a case of this kind if it came under his notice. But the operative means of relief is described in such a manner as to leave some doubt in the reader's mind which method the author recommends; and no inference can be drawn as to whether chloroform should be given for this most painful operation. It cannot be performed effectually in the same rapid manner in which the tonsils are removed, and we know that some difference of opinion exists in practice upon this point. Dr. Jones rightly condemns the use of chloroform for tonsillotomy, but he says nothing ubout anæsthetics in the case of adenoid growths. Granulations and caries of the tympanum do not, in our opinion, receive the attention they deserve, considering the importance of their treatment and prognosis; whilst perforation of the membrane, which might often be left alone, is treated with scarcely any reference to the granulations which so often exist in the tympanic cavity, and which may themselves be dependent on disease of the bone. The reader will find no help in the diagnosis of cerebral abscess in ear disease, nor any opinion as to the position most favourable for the trephine. On the other hand, the chapter on "Some Affections of the Internal Ear" is fully and ably written, and the book, taken as a whole, will be found a safe and useful guide to the busy practitioner in the more common diseases of the ear and naso-pharynx.

Agriculture in some of its Relations with Chemistry. By F. H. STORER, S.B., A.M., Professor of Agricultural Chemistry in Harvard University. Two volumes. London: Sampson Low and Co. 1887.

This seems to us the very book that was wanted by all interested in scientific agriculture. It is full without being diffuse, thoroughly scientific in tone and treatment without needless technicality, and so well written and arranged that it can be understood and used as a text-book by all who have acquired a sound elementary knowledge of chemistry and physics. The transcendent importance of agricultural chemistry was recognised from the time when chemistry became an exact science. Davy was among the first to help it, and from that time in England and abroad many an illustrious name has been associated with it. At the present day the study is more important than ever, for hard times have fallen upon our farmers, and it is only by accurate scientific knowledge joined to prudence and industry that they can hold their own. It would be impossible to enumerate even the most eminent of those who have worked in the field, but such names as Boussingault (so lately lost to us), Liebig, Stöckhardt, and Hellerhegel on the Continent, and Lawes and Gilbert, Way, Voelcker, Church, and Warrington in England, can hardly be omitted. In collecting together, summarising, and applying to the needs of to-day the labours of these and countless other workers Professor Storer has conferred a genuine service upon mankind.

The earlier chapters of the book deal with generalities, the relations of soil to air and water, the movement of water in the soil, the nutrition of plants, the selective power of soils, the influence of heat and light, the formation of soil from rock, the chemical changes produced by certain constituents of soil, and so on. There are, of course, some errors and omissions, but the whole history is well told, and suggestive as well as instructive. Here, and indeed throughout the book, we are reminded of the intimate connexion between agriculture and sanitation. The perfection of each would be reached if we could follow the well-known adage, "The rainfall to the river, the sewage to the soil." Among the physical conditions prominence is given to the capillarity of the soil, a most important agent in vegetable nutrition. Too fine division diminishes capillarity; much kneading and puddling is therefore bad, and earthworms are pronounced pernicious. It is strange that Darwin is not quoted on this last point, but there is no real discrepancy between the statement as it here stands and Darwin's great discoveries, for although the worm is a valuable agent in forming and disintegrating soils, he may, and no doubt often does, overdo his part.

A large portion of the book is, of course, devoted to manures: first, the pure fertilisers, such as phosphates, nitrates, and ammonia, and afterwards the more complex kinds—guano, stable dung, sewage, &c. As an example of the simple and practical character of the book, we may quote a few words on the subject of fish manure. After describing the different kinds of fish manure or "fish guano" made in America and elsewhere, and explaining the great value of all of them, the writer continues:—

"There can be no doubt that in the future, when the increase of population shall enforce a more intelligent agriculture, the drying of fish scrap will become a highly important branch of industry. It bears even now very curiously upon the question of utilising the sewage of cities. The reproach has often been made that the modern system of removing filth from cities by means of waterclosets and sewers flowing to the ocean is wasteful, unphilosophical, and wrong. But it appears from what has just been said, that such censure is hasty and ill-considered. So long as a clean, innocuous, and concentrated manure can be got from the sea in the shape of fish scrap, at less cost of money, comfort, labour, health, and life even than would have been expended in transporting the city filth to the farm, or in converting it into transportable form, it would be mere folly for the farmers to waste their energies upon the sewage."

This is substantially the argument of Sir J. B. Lawes, whose opinion should have been quoted. It has for the future, if not for the present, very great importance. Only one analysis of fish scrap is given, and we wish that others could have been added. Doubtless this and other deficiencies will be rectified in a second edition.

It does not lie in our province to discuss in detail the purely agricultural portion of the book, such as the rotation of crops, the management of farms under different conditions of soil, climate, and water, and the treatment of particular crops—barley, oats, and grass. It is curious, however, that a separate chapter is not given to wheat, and we should have been glad to have heard more of the management of root crops. The chapters devoted to pastures and the making of hay are valuable. It was of course impossible to include everything. The intelligent student of agriculture will be deeply grateful for what he has got, and if he masters the book he will have learnt much, and have attained the rudiments of a really scientific knowledge of his calling.

AT the annual meeting of the subscribers to the Royal Cornwall Infirmary, held at Truro on the 12th inst., an increase in the numbers of both in- and out-patients during the past year, as compared with previous years, was reported by the committee.

BRITISH MEDICAL ASSOCIATION.

FIFTY-FIFTH ANNUAL MEETING,

HELD IN DUBLIN, 1887.

PATHOLOGY.

(*Concluded from page 333.*)

AT the meeting on Thursday, Aug. 4th, Dr. Samuel Gordon, President, in the chair,

The PRESIDENT stated that he had no desire to inflict an address on the Section, but he wished to remind the few and inform the many that Pathological Societies originated in Dublin. In October, 1838, the Pathological Society of Dublin was founded, mainly through the efforts of Stokes and Robert Smith. The example was followed by Philadelphia and London. The President then traced the history and described the objects of the Society, and concluded by saying that its labours filled twelve large volumes, and the Society then merged in the new Academy of Medicine and Surgery.

Etiology of Chlorosis.

Dr. FOOT introduced this subject. He dissociated it from the comprehensive group of Anæmiæ, and touched upon the fundamental influence of age and sex, alluding to its relationship to precocity of menstruation. He invited a discussion as to whether it was due to a temporary disturbance of hæmatopoiesis or to arterial hypoplasia. After a few remarks by Dr. Anderson, the President called upon Professor Unna of Hamburg, to read his paper.

The Micro-organisms of Lepra.

Professor UNNA reviewed the opinions previously held on the pathology of leprosy. His remarks were then principally confined to the structure of the *bacillus lepræ* and the relation of the bacillus to the tissue elements. He had investigated very carefully the action of various staining reagents and different methods for colouring the bacillus. He described a modification of the method of Gram. By the action of the different dyes he was led to believe that the organism was not a bacillus, but that it consisted of a chain of cocci within a double sheath. When the bacilli were aggregated together, the outer capsules or glœa-masses fused together, and so gave the appearance of micro-organisms within the so-called leprosy cells. The leprosy cells, according to his view, were not animal but vegetable structures, and represented the fused capsules of the micro-organisms of leprosy. From these observations he regarded the term bacillus as untenable, and considered that the leprosy micro-organism should be called a *streptococcothrix*. Professor Unna then demonstrated a series of microscopical preparations.—Professor CROOKSHANK congratulated Professor Unna on his excellent paper, and on the fluency with which he had delivered it in English. His preparations also were very beautiful, but they did not convince him that the interpretation of them was on all points correct. He instanced the case of the bacillus of anthrax as one in which very peculiar appearances could be produced sometimes by the method of Gram. The iodine contracted the protoplasmic contents of the bacillus, and gave it a granular or beaded appearance. The beaded appearance of the tubercle bacillus was well known, and the leprosy bacillus was well known to be beaded also. But this appearance was very varied in the leprosy bacilli. In some cases there were three or four granules in a rod; in other cases there might be one only, which was sometimes situated terminally. In other rods, again, there might be two or three granules irregularly placed. On this account he thought it was misleading to speak of "cocci chains," and he preferred the old term *bacillus lepræ* to *streptococcothrix*.—Dr. THIN considered that the ovoid bodies seen in leprosy bacilli were spores. He had found the bacilli clustered in bodies with a rounded outline, which he considered cells. He had also found the bacilli in leucocytes in sections of the epiglottis, the leucocytes showing distinct nuclei. Dr. Beaven Rake, on examining juice from leprous nodules, found the bacilli within distinct cells. He considered the best results would be obtained from the examination of fresh specimens.—Dr. ACLAND said it was hardly fair to come to any definite conclusions from Professor Unna's specimens, as they had not been able to provide him with a sufficient number of high powers. But having examined the specimens, he was compelled to say that he did not hold the same views as the writer of the paper. He did not consider it a matter of great importance whether the organisms were in the cells or exterior to them. It was probable that they were found in both positions, but he was inclined to think that it was remarkable that the appearance of the organisms had been so variously described. Some looked upon them as an aggregation of cocci within a delicate membrane, others as bacilli, and that the appearance was due to the method of preparation. He agreed with Dr. Hansen of Bergen that the organisms were bacilli, and that in many cases they were within the cells.—Dr. SIMS WOODHEAD said that, after looking at Professor Unna's preparations, he thought that his views were not so untenable as they were regarded by previous speakers. He had found various bodies in fresh juices which closely resembled the appearances described by Professor Unna. He did not agree with a previous speaker that it was unimportant whether the organisms were found in the cells or in the lymph spaces, because if they attacked the cells it is probable that degenerations would occur much more rapidly than they do. He was inclined to support the views of the reader of the paper.—Professor UNNA replied.

A Report of fifty-eight specimens of Chronic Inflammatory Disease of the Uterine Appendages operated on by Mr. Lawson Tait during 1886.

Dr. J. ST. CLAIR BOYD gave a description of the pathological appearances of the organs removed. The great feature was occlusion of the infundibular extremity of the tube, and associated with this in the great bulk of them was closure of the uterine mouth. The nature of the contents of the tube seemed to be a matter of accident governed by the stage of the process at which the removal had taken place. The formation of tubo-ovarian cysts was now attracting considerable attention, and the specimens shown completely confirmed the views which Mr. Lawson Tait had already published.—Mr. TAYLOR spoke of the importance of determining what was meant by the term "tubo-ovarian cyst." He considered that there were at least three kinds which he defined, and there were possibly others.—Dr. JACOB and Mr. LAWSON TAIT joined in the discussion.

Elephantiasis induced by Posture.

Dr. MAPOTHER described the case of a lady aged eighty, who had her knees and hips so flexed owing to rheumatic gout that lying on the back was unendurable. The legs thus constantly dependent developed a condition of elephantiasis. After describing in detail the condition which resulted, Dr. Mapother considered that if posture, as he contended, was a factor in the production of elephantiasis, elevation, friction upwards, and compression in the elastic bandages should be hopeful measures during the stage of inflammatory œdema.—Dr. SIMS WOODHEAD said the paper was most opportune, especially in relation to the blockage of lymphatics by organisms in leprosy. He thought all the changes had been most accurately described.

Cases of Permanently Displaced Head of Humerus and Abnormal Growth of Nail.

Dr. MOORE, in describing the above, said the first case arose in a child of six months by being thrown on the ground. The lad was now fifteen, and the chief points of interest appeared to be the wasting of the shoulder muscles, the low position of the head of the humerus, the facility with which the latter could be partially replaced, and its immediate displacement by gravitation. The second case occurred in a patient aged sixty-nine. There was a peculiar horn-like growth of the thumb-nail, and the phalanx of the thumb appeared to have been lost by suppuration.

On the Fourth and Fifth Dorsal Vertebræ in Health and Disease.

Dr. HARKIN, after a few general remarks on the subject of neurology, said that he was interested in that small area of the spinal cord limited and covered by the fourth and fifth dorsal spines, the very centre of the spinal column, which, whether in health or disease, is gifted with functions and phenomena peculiar to itself. That this limited area constitutes a zone of latent hyperæsthesia, present in every case of acute hysteria, chorea, trifacial neuralgia, and facial

Digitized by Google

paralysis, and other neuroses, had been known to him for the greater part of his professional life, and also that treatment applied solely to these apophysial points rapidly cures those diseases; but why a blister applied over the fourth and fifth dorsal vertebræ rapidly cured tic douloureux, or put an end at once to the vomiting of pregnancy, he could not explain to his own satisfaction, nor could eminent neurologists to whom he applied, including Brown-Séquard, throw any light on the subject. The almost universal existence of spinal hyperæsthesia over these points in health as well as disease is still more difficult of explanation. This spinal peculiarity he had found in every class, in the army, in the constabulary, in reformatories, male and female industrial schools, and in his ordinary *clientèle*, and private patients and friends. Some of his medical friends, while acknowledging its frequent presence even in the healthy, fail to evoke symptoms of undue tenderness in every case from want of faith or courage in applying the test—viz., the knuckle of the middle finger over all the dorsal spines. The clinical results after blistering are more freely acknowledged. Dr. Prince gives some remarkable cures effected by a blister over the fourth and fifth dorsal spines—among the rest one in a woman aged thirty-five, suffering from cervico-occipital neuralgia for five weeks, great tenderness over the cervical vertebræ, and rigidity of the muscles, with an expression of prolonged suffering. Dr. Browne, of Belfast, gives a case of facial paralysis in a man, of nine days' continuance, permanently cured by the application of a small blister over those vertebræ, and one of a lady suffering from coryza, with continuous discharge of clear mucus from the nares, and fits of sneezing which had troubled her for twelve months, and for which he had prescribed various remedies without effect. He applied a blister over the spine, and next day the discharge from the nares had permanently ceased.

At the meeting on Friday, Aug. 5th, Dr. Samuel Gordon (President) in the chair,

Dr. SIMS WOODHEAD described and exhibited large sections of Morbid Conditions of the Lungs by means of the magic lantern. The demonstration attracted a large audience.

Micro-organisms associated with Malaria.

Professor CROOKSHANK read a paper on this subject. He mentioned that his attention had been drawn to this subject by his discovery of flagellated monads in the blood of rats. This made him anxious to study the flagellated organisms described by Laveran in the blood of cases of malaria. Professor Crookshank reviewed the work of previous investigators, and described the *bacillus malariæ* of Klebs and Tommasi-Crudeli. He pointed out the fallacies in the views of the last-named, and considered that the researches of Laveran, Richard, and Marchiafava and Celli were more reliable. Through the courtesy of Professors Golgi and Marchiafava he had been able to confirm the observations of these writers, but he had not had an opportunity of studying the flagellated bodies. These occurred very rarely, and from the account given by Professor Marchiafava he should say they were not at all like the organisms in the rat. He was now directing his attention to the cases of malaria in this country, and hoped to have more to say on a future occasion for the present he was glad to have the opportunity of demonstrating the peculiar structures known as the *plasmodium malariæ* and the semilunar bodies of Laveran.

Various questions were asked by Dr. Russell, Professor Macfadyean, and Dr. Acland, to which Professor Crookshank replied.

Sectional Anatomy of Inguinal Hernia.

Dr. CUNNINGHAM contributed a paper on this subject. It was illustrated by a series of frozen sections, and communicated in the absence of the author by Dr. St. John Brooks. The sections were made through the body of a subject suffering from congenital inguinal hernia. After some remarks on abdominal anatomy in general, he showed how the peritoneum was displaced in the sac of the hernia, and explained how the gubernaculum testis played an important part in the formation of the hernia. He drew attention to the great accumulation of fat in the mesentery which was found in the sac of the hernia, and showed some interesting photographs of the sections.

Tubercle in the Dairy.

Dr. SIMS WOODHEAD and Professor MACFADYEAN made a communication on this subject. They gave the results of a series of observations on tubercle in cattle and in milk. They pointed out that tubercular ulceration and tabes mesenterica were comparatively common in children, and especially where there was impaired digestion. They looked for the cause of this in tubercular cattle. In 623 cases from thirty-seven dairies they found thirty-one in which there were diseased udders. In most of these they found micro-organisms, but in six only were tubercle bacilli present, and then very sparsely. In the udders of certain cases they found bacilli present in large numbers. They did not lay very much stress on their observations, but they thought that more attention should be paid to this condition by inspectors, and a careful inspection made of the udders of dairy cows.—Dr. W. RUSSELL thought there was very little doubt as to the possibility of the communication of tuberculosis by milk. The question of nidus necessarily arose. In the case of children perhaps the commonest affection among them was gastro-intestinal catarrh, and in such a condition there was probably a suitable nidus. If the continued observations of these observers should conclusively show that tubercle could be transmitted by milk, there could be no doubt of the duty devolving upon public authorities to have the cows regularly examined.—Dr. PURSER asked whether tuberculosis was common in the human mammary gland.—Dr. ACLAND stated that he had made many examinations of milk from tuberculous women, and had never found any bacilli. He did not remember having seen a single case of tubercular disease of the breast, although he saw many cases of women suffering from advanced disease of the lungs who continued to suckle their children.—Dr. GILBERT KIRKER asked as to the sanitary condition of the sheds, to which Professor MACFADYEAN replied.—Mr. HEDLEY thought that this investigation bore significantly on food supply. Cheese might become an agent in infecting people, unless the process of manufacture destroys the germ. Butter also might convey the disease.

Erythema Nodosum a Specific Infectious Disease, and the Bacteria found in the Disease.

Dr. MANTLE read a paper producing clinical evidence which he thought was suggestive of erythema nodosum being a specific disease. He adduced facts showing its development in the midst of scarlatina and in measles, but particularly pointed out its relationship with the former. He had seen an epidemic of erythema nodosum in which children were chiefly affected, and during this epidemic a disease of a very similar nature took place in swine. He quoted the opinions of Trousseau and Hebra, who regarded the disease as a specific infectious disease. He had examined five cases for bacteria, strict antiseptic precautions having been taken to prevent contamination, and had in each case found bacilli; but he did not argue from so slight evidence that the organisms were by any means the cause of the disease, but merely thought the fact perhaps suggestive.—Dr. BROWN said that in ten years his experience proved that erythema nodosum was not what we understood as an infectious disease. He had seen but very few, if any, cases of erythema nodosum in male adults. Nearly all cases occurred in young women, and associated with menstrual derangement, and by giving iron and aloes the case is soon cured. That there is a close relation between scarlet fever and rheumatism most medical men will admit. Frequently there is rheumatic pain in the joints in scarlet fever which can be relieved by salicylate of soda.—Dr. ARCHER said he was somewhat surprised to hear that erythema nodosum was an infectious disease, but, at the same time, to hear the theory propounded that it depended on a bacillus was not at all surprising to him, as it was the fashion now to ascribe every disease to micro-organisms. He had read a good many papers on the subject, and he did not believe that in any case had proof been brought forward to show that they were anything more than the effect of the disease.—Professor CROOKSHANK said that Dr. Mantle had laid stress on the supposed infective nature of erythema nodosum, and then had described a bacillus in connexion with the disease. This naturally led the last speaker to run away with the idea that this bacillus was characteristic of the disease, and that Dr. Mantle suggested a causal relation. No evidence whatever had been brought forward in support of the latter belief. As no preparations of the bacillus, in the blood, or from cultivations, were shown under the microscope, but only tube-cultivations, Professor Crookshank was only in a position to say that the bacillus presented on cultivation a reticulated pellicle, which was also a character of the *bacillus epidermidis* and other bacteria. No doubt precautions had been

Digitized by Google

taken against contamination, but that was not sufficient when the skin was involved, for the only means of avoiding error was to make control experiments by examining the organisms ordinarily present on the skin. He pointed out that Dr. Mantle had last year brought forward a bacillus which he associated with gonorrhœal arthritis, and this presented precisely the same cultivation appearances. In the absence of further proof he could only regard these as saprophytic bacilli. Professor Crookshank was of opinion that it was very praiseworthy for a medical man busy in practice to undertake these researches, and so keep up with the times, and he knew there was difficulty in making inoculation experiments. He urged, in such cases, the necessity for co-operation with a competent observer who had permission to make such experiments. The necessary evidence would then be forthcoming, and such a co-operator would doubtless suggest where observations must be controlled, and thus fallacies would be prevented from getting the upper hand. It was really a grave responsibility to publish such incomplete researches, because it led the sceptical to making such remarks as those which had fallen from the lips of Dr. Archer. Those remarks were a challenge to bacteriology, and he could not leave them unanswered. He desired, therefore, to emphasise the fact that bacteriologists, properly so called, were strongly opposed to any such fashionable or enthusiastic views in connexion with the study of pathogenic micro-organisms. Further, the statement that there was no proof to show that they had any causal relation was only an instance of how unjustifiable it is for anyone to dogmatise without any practical knowledge of the subject whatever.—Dr. ACLAND was surprised to hear such statements as Dr. Archer's in the Pathological Section, and instanced the case of anthrax, or woolsorters' disease, as one in which the causal relation of the micro-organism was universally accepted.—The discussion then became general, the weight of opinion being that no evidence had been adduced to prove the views of the writer of the paper.

Organisation of the Thrombus formed in an Artery after Ligation.

Dr. SHERIDAN DELÉPINE gave a short abstract of his paper on this subject. He pointed out that after ligation of one of the large arteries of the sheep the blood coagulates in the part of the artery where circulation has become impossible—i.e., between the seat of ligature and the first collateral branch above. This clot is not formed all at once. For nearly ten days the clot contracts; spaces are thus formed between the walls of the vessel and the central clot, and into these spaces fresh blood rushes, coagulates, and contracts in its turn; this causes a first stage of spurious or false vascularisation—i.e., vacuolation. The intima proliferates, the proliferation being most marked in the region corresponding to the proximal convex surface of the clot. From this point, especially, the cells of the intima grow into the clot, which is slowly absorbed as they advance. At the same time some of the cells are arranged so as to form a network of impervious embryonic vessels in the midst of the other cells and of the unabsorbed parts of the clot. At the end of the second decade the clot is practically entirely transformed into young connective tissue with embryonic vessels, and the vascularisation up to that time may be said to be rather potential than actual. As the clot is becoming absorbed, the space occupied by it gets smaller, the proximal surface of the plug of connective tissue taking its place becomes depressed, funnel-shaped, and the embryonic vessels begin to show a distinct lumen. By this time the muscular coat of the disused portion of the artery has almost entirely degenerated. Small cells and embryonic vessels are found penetrating into it from the intima and adventitia; these embryonic vessels meet, and when ultimately they become channelled, communication is established between the lumen of the artery, the vasa vasorum, and other vessels surrounding the artery through the vessels newly formed in the plug replacing the thrombus, and true or actual vascularisation at last may be said to exist.—Dr. WOODHEAD and Dr. ACLAND took part in the discussion, the latter drawing attention to Mr. Ballance's researches in connexion with this subject.—Dr. DELÉPINE replied.

The PRESIDENT regretted that time would not allow the Section to continue, and announced that Dr. Knight's paper "On certain Pathological Conditions of the Blood, with especial reference to their Action as Factors in the Manifestations of Empyema, Chlorosis, and Cutaneous Diseases," would be taken as read.

THE COLLEGE OF STATE MEDICINE.

As some of our readers may be aware, though we believe no public announcement of the fact has hitherto been made, an institution has been recently incorporated under the above-named title with the following objects:—1. To found, establish, and maintain, in or near London, an institution, to aid the theoretical and practical investigation and study of Sanitary Science, and of all matters relating thereto. 2. To aid the theoretical and practical investigation and study of other branches of State Medicine. 3. With a view to effecting these objects, to appoint professors to institute lectures and demonstrations, to issue publications of the Transactions of the Association, to found chemical and pathological laboratories, and a library. 4. To do all such other things as may from time to time be incidental or conducive to the attainment of the objects above set forth, or any of them.

It has been felt that in view of the increasing demand which is now being made for Public Health qualifications, some such provision as the above College is intended to afford was necessary; and although at most of the medical schools a course of lectures is given in Hygiene, it was felt that the class of men who wish to avail themselves of the instruction necessary for such diplomas would prefer attending an institution separate from any existing school, the candidates generally being gentlemen in practice or those who have for some time been qualified.

The Council of the College consists of Sir Joseph Fayrer, K.C.S.I (chairman); Sir John Watt Reid, Director-General (Navy); Sir Thomas Crawford, Director-General (Army); Sir Guyer Hunter, K.C.M.I., M.P.; Sir Henry Roscoe, M.P.; Sir Douglas Maclagan; R. Quain, M.D., F.R.S.; E. Klein, M.D., F.R.S.; Surgeon-General W. R. Cornish, Physician to Her Majesty the Queen; R. Brudenell Carter, Esq., F.R.C.S.; Surgeon-Commandant Cantlie; and others. We understand also that provision is made for seats on the Council, as *ex officio* members, of the presidents of existing Public Health Associations—such as the Sanitary Institute, Public Health Medical Society, &c.

There are to be two grades of membership—the Fellowship and Associateship. The former is to be conferred upon gentlemen eminent in any branch of State Medicine; the latter on those students of the College recommended for it, such students having first obtained a registrable qualification in Public Health. It is intended, however, in the first instance, to invite all gentlemen to become Associates who have obtained a Public Health qualification.

The course of instruction is not yet definitely arranged, but we understand it will include occasional lectures from eminent sanitarians, a course of lectures on Bacteriology, a course of lectures on Hygiene, and laboratory instruction.

The offices are at 26, King William-street, Strand, W.C., which, it will be noted, are also the offices of the Volunteer Medical Association and the headquarters of the Volunteer Medical Staff Corps; and we are informed that opportunities will likewise be afforded to Volunteer medical officers to get the instruction necessary to obtain the proficiency certificate.

THE THERAPEUTICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—I have the pleasure of announcing that Dr. Sydney Ringer, F.R.C.P.L., F.R.S., has kindly consented to accept the office of first President of the Therapeutical Society, provided that we can arrange the date of the inaugural address to suit his various engagements. I am sure that all the members of the Society will read this statement with great satisfaction. To have secured the leadership of such a world-known man as Dr. Ringer is to make the Society proof against adverse criticism, and to make it certain of success. By an error of mine in a former letter, which you were good enough to publish, I styled Dr. Rayner President of the Medico-Psychological Society, whereas I ought to have written *formerly* President. Again thanking you for allowing me the use of your valuable columns,

I remain, Sirs, faithfully yours,

Longridge-road, S.W. A. GEORGE BATEMAN, M.B.

THE LANCET.

LONDON: SATURDAY, AUGUST 20, 1887.

THE subject of sea-borne cholera in connexion with British measures of prevention, as opposed to European measures of restriction, was brought before the recent meeting of the British Medical Association in Dublin by Dr. THORNE THORNE, who acted as one of the delegates of this country at the International Sanitary Conference which was held in Rome two years ago with a view to the establishment of a universal code for preventing the importation of this disease; and the present occasion, when cholera is prevalent at several points in the Mediterranean with which the ports of this country are in communication, is an opportune one for considering how far the two methods in force for the prevention of cholera may be trusted to effect their intended purposes. The paper in question states that these two systems are in distinct antagonism to each other. The one which Europe as a whole trusts to, and to which, under the lead of the French, she has repeatedly given her assent at international gatherings, is a strict quarantine, disguised since the Rome Conference under the style of a "period of observation." The other is our system known as that of "medical inspection." The one, according to the author of the paper in question, "says to cholera: 'Hitherto shalt thou come, but no further;' the other, based on experience as to what is practicable in controlling the march of such a disease as cholera amongst civilised communities, has, above all, aimed at the removal from the midst of the people of those conditions which are essential to the spread of the infection."

The European epidemic of 1884-87 has afforded a means for testing the value of those alternative systems. France, foremost amongst quarantining nations, knew of cholera amongst her troops in Tonkin, but cholera entered France by means of infected transports; Italy then put France into quarantine, but cholera invaded her territory by means of coast and frontier provinces; Algeria insisted on rigorous measures of quarantine, but these did not avail to keep cholera from her ports; Spain dealt likewise with the infected countries, but her people suffered a terrible mortality from the disease, which reached her by means of a sea-coast province. In other words, quarantine, with all its modern improvements, turned out to be nothing more than a measure of useless restriction which was utterly disregarded by the advance of cholera. This recent experience is entirely in keeping with the previous history of cholera in Europe, and it fully justifies the irrevocable decision of this country to abandon a system more characterised by its barbaric and inhuman qualities than anything else. France, however, apparently clinging to the system for the sake of form, still advocates it in every capital where conferences assemble; and, knowing that the ten days' quarantine system advocated at Constantinople in 1866 has failed, and that the reduction to a seven days' detention proposed at Vienna in 1874 has shared no better fate, would imply that a still further reduction to five days, such as her delegates proposed at Rome, is, after all, the remedy. In the face of this, it is hardly a matter of wonder that the Rome Conference adjourned *sine die*.

We have so often referred to the real advantages of our alternative system, that we need only briefly summarise what is and has been done under it. All sick of cholera or diarrhœa are dealt with and isolated at our ports; but the healthy are not herded with the sick, as is done under a quarantine system. They are allowed to go where they will, provided they submit to proper supervision, by giving the address of the destination to which they are travelling. These precautions form, however, only the fringe of our system of prevention. Our population, knowing that the Government will no longer pretend to guarantee any measure of safety by drawing a quarantine line around the country, have of their own free will set themselves to remove from their midst those conditions under which imported cholera can alone spread; and, according to Dr. THORNE, they have, apart from all Government dictation, spent during the past ten years, by way of loan or in current expenditure, over eighty millions sterling, for purposes mainly of a sanitary character. When quarantining countries can give evidence of their faith in their alternative system by submitting to any such expenditure, then it will be time enough for them to urge that their system merits further consideration at our hands. Up to the present time, and this even in the Red Sea, which is looked upon as the gateway by which cholera may at any time enter Europe, the quarantine stations are not even provided with the common decencies of life.

Since our system of medical inspection came into operation it has gone hand-in-hand with a steady sanitary progress far exceeding anything to be met with in those European countries where the inhabitants are led to believe that quarantine restrictions will be imposed for their protection in times of danger; it has been accompanied by a great diminution in mortality, and it has spared the inhabitants of this country from an untold amount of misery and destitution, which "is the more burdensome because it follows in the track of preventable disease and death." That our system is complete we do not for a moment pretend, and we would make no boast of the fact that imported cholera has on each occasion, for many years past, been at once checked in this country; but we do hold that the experience of the past few years has once again indicated the uselessness of quarantine and the great advantages of the system we have substituted for it. Quarantine has "a blighting effect on sanitary progress"; it leaves a people unprepared to face a disease which disregards the antiquated barriers which nations have opposed to its extension, and so it prepares the way for panic. On the other hand, the steady progress of true measures of prevention tends to impart that feeling of confidence which is of such value in the face of an impending epidemic, and at the same time it promotes the healthiness and well-being of the population.

FOR a large proportion of what are regarded as people of the "better" classes in this country there are scarcely any regular "meal-times." Those who are able to dine at a fixed hour for the most part take breakfast, luncheon, and

Digitized by Google

any other meals they may have, at odd times, more or less uncomfortably. Paterfamilias rushes his morning meal to catch a train or keep an appointment, snatches his mid-day meal how he can, and when he contrives to dine at home or to keep a dinner engagement, is either hurried or late, and therefore generally more or less ill-prepared for the really serious physiological feat of eating at one sitting enough to supply nutriment to the organism for the greater portion of the succeeding twenty-four hours, let what may be taken out of brain and body during that period; for the very large class of busy men to whom we are now alluding take very little to eat, although many consume a proportionally large amount of stimulating beverages when they are not feeding. The unmarried men of this order are even more irregular in their mode of taking food than their elders. Albeit they may be "diners out," they do not for the most part eat. Even admitting that the majority of men have been in times past, if they are not now, in the habit of eating too much, it is astonishing to observe how very little, with all his parade of appetite, and real or pretended *gourmet* airs, the average man of pleasure or fashion actually consumes. Materfamilias and her daughters are equally irregular in the supply of their needs in the matter of nutrition. They rise late, or, if not that, they either ride or walk before breakfast in a way differing greatly from the old-world practice of taking healthful exercise with a view to eating a good breakfast. The prevailing whim is the affectation of a continental *penchant* for breakfast about noon, which means an early luncheon, but for the most part falls short of an adequate mid-day meal. In short, women-folk "peck" at a late breakfast, at luncheon, and again, more demonstratively, at dinner, counting it a feminine grace to have small appetites, and almost vying with each other in their pretty winning way to pass nearly all the dishes. Doubtless in some way women eat enough, but their food is so taken as to digest with great difficulty and not a little distress. Probably most of the forms of dyspepsia increasingly common among women may be traced as their efficient cause to the habit of perpetually worrying the stomach with food, instead of feeding regularly at timely meals.

It has been hinted that, perhaps, we ought to assume that too much in the aggregate, or too bulky food, is habitually taken. In the ideal future of our species' development, man may perhaps take his food in the highly concentrated form of pastils or lozenges, or, dispensing altogether with the gastric organ, he may see fit to be nourished by some irregular mode of absorption. For the present, however, and for some generations to come probably, man will be compelled to take his food *per orem*, and the stomach is, and will continue to be, sufficiently important an organ in his economic apparatus to deserve, as it demands, deferential consideration, and such wise treatment as may minimise its labour and reduce to the least point the wear and tear it undergoes in fulfilling the systemic requirements. The first condition of health in a hard-working organ is regularly remitting strain and work, and punctually recurring periods of rest with opportunities for recuperation. To ensure the satisfaction of this orderly need there must be regular "meal-times," and we are well persuaded that the majority of dyspeptics would find their disabilities in the work of digestion greatly reduced if only they would make it a rule to eat regularly, moderately, and slowly. Irregular meals, at which the stomach is overloaded with materials consumed in haste, are the fruitful sources of distress and inconvenience in the function of food-taking. Indeed, the time and manner of taking food are almost as important as the specia character of the food we take. A dietary table should always particularise the hours for eating and drinking, and those who undertake to minister to the needs of the dyspeptic ought, we think, to lay very great stress on the time and manner of food-taking. The most nutritious diet loses half its value—if, indeed, it be not absolutely wasted—when it is thrown into the stomach, as it were, in shovelfuls, at odd times, without the smallest regard for the condition of that organ or the presence or absence of digestive secretions which are essential to the due performance of the alimentary functions. Economy, health, and in a large measure happiness, depend very seriously on the wise ordering and regularity of our meal-times; and those who are wise will see to it that this primary obligation of a physiological life is duly discharged.

FROM a Memorandum which has been issued by the Local Government Board, it would appear that the central authority have been in communication and in personal conference with the authorities for the city of Oxford on a matter which is becoming of primary importance as regards the future healthiness of many of our towns and cities, and that as yet Oxford does not see its way to initiate a change which is very urgently needed. The matter relates to the provision of a reasonable amount of open space behind new dwelling-houses, and the Local Government Board, having failed to convince the Oxford Board that injury was being done by the want of a proper bye-law to deal with this subject, instructed Dr. THORNE THORNE and their architect, Mr. GORDON SMITH, to inspect the city and its suburbs, and to confer with the local authority on the subject. The result of this visit is set out in the Memorandum in question, and it appears the reverse of creditable to those in whose hands the future interests of Oxford are vested.

The model code of bye-laws issued by the Local Government Board includes a clause requiring that all new buildings shall have a certain amount of open space in front and to the rear. The space to the front is almost always provided by the street itself; that to the rear has to be provided on the land belonging to the house. The principle embodied in this requirement is one which must command the assent of all sanitarians, for without space to the front and to the rear of a house there could be no windows in those positions, and no proper ventilation of the dwelling; besides which, the continuity of the open spaces is essential to that due ventilation around and about houses which is contemplated under the Public Health Act. The actual minimum space to the rear asked for under the model bye-law is a space measuring fifteen feet by ten feet, and even on this a closet and an ashpit may be placed. As the house increases in height, so does the required open space increase in area. Such a minimum space appears to be little enough, and there are a number of sanitary authorities who

Digitized by Google

are not content with so little, and insist on a larger amount. But the Oxford authority declines to adopt it, and regards it as excessive for the purposes of the city.

The main difficulty arises with regard to the re-erection of existing houses, for, as the inspectors state, the houses in the principal parts of Oxford are densely crowded together, very many covering the entire area of their premises, and others having to the rear what are in effect mere shafts inadequately serving to admit light and air. Indeed, a bird's-eye view exhibits hardly anything but roofs and buildings. The inspectors appeal to the Ordnance maps in proof of their statement, but they add that since these maps were drawn the evil has materially increased, and instances are given to show that a city with courts and alleys already to excess is getting worse and worse in this respect. Here lies the grave evil to be met, and the question which Oxford has had to decide is, whether the mischief is to go on unchecked, or whether an effort is to be made to remedy it. So far Oxford's health representatives have decided to allow the existing evil to grow into a worse one; and they have done this in the face of offers of compromise, which, if they err, do so on the side of excessive leniency. Thus, the difficulty of dealing with the undue aggregation of houses in certain parts of Oxford was admitted, and to meet it, it was suggested that the bye-laws dealing with this subject might be so framed that they should not affect re-erections, provided the new buildings did not exceed the present ones either in height or in extent of ground covered. Now, considering that some existing houses have no open space at all belonging to them, concession could hardly go further. But the modification was not assented to, one reason being that it would cause irregularities in the heights of adjoining frontages. How this difficulty is to be overcome apart from bye-laws we do not know, for no authority has power to require uniformity as regards height of adjoining houses.

Failing this, the inspectors proposed another compromise, and this was that the area of the city in which the main difficulty arises should be defined, and that this area should be altogether exempt from the operation of the new bye-laws. This was met by proposals following one on another that this and that area should be exempted, until it was evident that the proposals submitted were altogether unreasonable. On this it was clear that Oxford declined any bye-law dealing with this important subject which could reasonably be assented to; and the conference had to be dropped.

The difficulty which has arisen at Oxford is certain to arise elsewhere, and sanitary authorities would do well distinctly to understand what their duties to the public are in this respect. Owing to a want of proper control in the past, houses have in many towns and cities become unduly aggregated together, and such houses have often, owing to the mere accident of position, and in no way owing to any expenditure on the part of their owners, acquired a value which is to a great extent fictitious. If such houses are to be rebuilt on a more expensive scale, and with the same or even a greater disregard to the requirements of public health, the difficulty of securing a remedy is indefinitely postponed; and the legalisation of a bye-law to prevent this evil is no more an interference with private interests than are numberless other provisions of the Public Health Act, which is throughout based on the principle that private interests must not stand in the way of the requirements of the community in the matter of health. Oxford, a centre of learning, disregards this, and that in view of the probability that its densely-crowded areas may become more crowded than ever, that its courts and alleys may be more confined than they ever have been, and that the breathing spaces which still remain behind the houses may be altogether covered over and shut in by loftier obstructions to ventilation than those which now exist. The result is to be deplored in the interests of future generations, and on those to whom the decision is due a heavy responsibility must rest.

THOSE very energetic persons to whose persistency we are indebted for the repeal of the Contagious Diseases Acts seem determined not to let the grass grow under their feet. They have altered the title of their Association. It is no longer the National Association for the Abolition of State Regulation of Vice, but the National Association for the Defence of Personal Rights. With this avowed object in view, they have addressed a memorial to the Secretaries of State for the Admiralty and War Departments, and to members of both Houses of Parliament. It is marked "important," and is a very remarkable document. The memorialists, having learnt that the Government have recently granted subsidies to certain hospitals for the treatment in special wards of women suffering from venereal diseases, desire to protest against any such use of public money. The reason assigned for this protest is original, if illogical. It appears that in 1875, just twelve years ago, representatives from twenty of the most active Associations for the repeal of the Acts met, and for *two* days carefully considered certain proposals then made for subsidising or maintaining lock hospitals or lock wards in hospitals, in lieu of the arrangements authorised by the Contagious Diseases Acts 1866-69. The result of this *two* days' deliberation, we are now informed, was a unanimous declaration in favour of admitting cases of venereal disease into general hospitals and infirmaries, as one among the many forms of suffering which it is the purpose of those institutions to relieve. It is also contended that the present House of Commons is bound by a vote of last year, which rejected an amendment of Sir JOHN KENNAWAY providing for the continuance of voluntary lock hospitals supported by the Government. The whole tenour of the memorial is, like most of the literature proceeding from the same source, inaccurate and misleading; ingenious, but very disingenuous. It would, indeed, be unworthy of notice were it not necessary to refute statements put forward with such persistency. The making of grants of money by the Government to lock hospitals and wards in Portsmouth and Plymouth was allowed without dispute many years before the first Contagious Diseases Act (that of 1864) was passed. The Westmoreland Lock Hospital of Dublin has been supported by a Government grant ever since its opening in 1792; and though it has been proposed to discontinue the annual grant, it is on the grounds of its not being a clinical hospital, and not because the principle of supporting such hospitals is condemned. Moreover, one of the strongest arguments used

Digitized by Google

against the Acts by their opponents was that the same, or even greater, results might be achieved by voluntary lock hospitals and wards. They also urged that if the Acts were only repealed, these latter would be liberally provided by the public. So far from this having been the result of their repeal, the Government have been practically compelled to make the grants objected to. The proposal to admit women suffering from venereal diseases into the wards of general hospitals and infirmaries, without distinction, is one the impracticable nature of which scarcely needs comment. To place a married woman infected by her husband with syphilis in the same ward with medical or surgical cases is a proceeding which could never be sanctioned by the managers of any hospital or infirmary; while to admit a prostitute, however penitent she might be, would be simply an outrage. Patients suffering from these diseases must be kept apart from other patients, in separate wards, with separate waterclosets, eating and drinking utensils, washing apparatus, and conveniences of every kind. These requirements are so obvious as to need no argument, and lock hospitals and wards must continue so long as venereal diseases prevail. The truth is, that the tide of public opinion is slowly but surely turning against those who caused these Acts to be repealed. Only a little more experience of the disastrous results which have followed will cause their restoration to be demanded with a force which will sweep away all opposition to the winds.

Annotations.

"Ne quid nimis."

THE INTERNATIONAL MEDICAL CONGRESS.

THOSE Europeans who intend to take part in the International Medical Congress are beginning to wend their way across the waters. The programmes are not yet given in much detail. The Congress will be opened by the President of the United States, at Albaugh's Opera House, on Monday, Sept. 5th, at 11 A.M. This very fact stamps it with an international character. It stands, too, in the series of International Congresses, and will represent to the world the state of medicine as a profession and an art. This fact is enough to invest the meeting with high importance, and to make us wish, as we do devoutly, that it may prove worthy of its predecessors, of the series of which it is a member, and of the great nation of which it is the guest. We are well aware that all has not gone smoothly with it, and that our brethren in the States have been keenly divided as to methods of procedure and questions of membership and precedence. We have no wish to judge between them; but we have never been able to see that the Congress can be treated disrespectfully, or even coldly, without the profession itself suffering. It ought to be the endeavour of all concerned to minimise differences, and even at the eleventh hour to make this Congress great and effective. Meanwhile we may call attention to a circular, issued by the New York Bureau of Information, which contains the following "instructions to visitors":—

"Washington is 200 miles from New York—six hours by cars. Foreign steamers to New York land at New York or at Jersey City and Hoboken, opposite New York. The New York Bureau of Information have engaged a reception parlour in the Hoffmann House, corner of Broadway and 25th Street. The Broadway car line, which is crossed by the car lines from all the steamboat landings, passes in front of the hotel. Rooms at the Hoffmann House, which is conducted on the European plan, can be obtained through the committee at a reduction of 25 per cent. One or more of the Reception Committee will be in attendance between 2 and 4 P.M. each day on and after August 20th. At other hours the clerk of the hotel will act for the committee. Members intending to attend the Congress are requested to send their names in advance to the Reception Committee, Hoffmann House, New York, so that the committee can secure for them reduced hotel and railroad rates."

CHOLERA RUMOURS.

RUMOURS of choleraic diseases in this country tend to arise at this time of the year. One instance occurred some three weeks ago at Newton-Poppleford, where Dr. Pullin, who has had experience of cholera, met with a case which terminated fatally in twenty-four hours, after presenting, according to his report, the symptoms of the Asiatic and malignant disease. The case was that of a farmer, who, after having indulged somewhat freely, was affected by the excessive temperature; and Dr. Pullin is reported to have set the disease down as due solely to the heat to which the patient had been exposed. The sanitary surroundings of the man's residence were excellent, and no other condition indicating any suspicion could be detected. Similar rumours also come from Marylebone, but the cases in question are properly classed amongst those severe diarrhœal affections of which a few always occur in England at this time of the year. The symptoms they not unfrequently present do admittedly most closely resemble many attacks which occur during a prevalence of true cholera, but this circumstance alone is no proof that the infective disease is in our midst, and it is important that those meeting with such cases should not cause unnecessary alarm by resorting to a nomenclature which is only intended to cover cases of the infectious Asiatic disease.

THE CASE OF ISRAEL LIPSKI.

THE extraordinary measures that are being taken to discover further evidence that may shed light on the Batty-street murder shows at least that there is still a considerable amount of mystery enshrouding the case. Many points now being investigated ought, in our opinion, to have been cleared up at the time of the trial, instead of being considered during the respite of the prisoner, who has to linger in suspense, with the gallows ever present to his mental vision. That Miriam Angel was murdered there can be no manner of doubt. It seems equally clear that in the first instance she was rendered insensible by blows on the temple, and afterwards suffocated by strong nitric acid. There is a strong chain of circumstantial evidence, which on the face of it tells strongly in favour of the conviction recorded at the Old Bailey, but it is not enough to warrant the death sentence being carried out that the facts fit the theory of Lipski's guilt; it must be shown beyond reasonable doubt that they are inconsistent with any other hypothesis. As regards motive we are not inclined to lay much stress one way or the other, as the proximate cause of crime is too frequently unknown, and of course still more frequently inadequate to the particular offence. Nevertheless, in this case the motive being entirely conjectural, as negative evidence it should on technical grounds be counted somewhat in favour of the innocence of the convict. If it could be conclusively shown that the door of the room in which the dead body of Miriam Angel and her supposed murderer were found was actually locked on the inside, and that it was impossible that the key could have been turned by some person outside the room, there would be an end of the case; but from the reported testimony it appears by no means clear that the door was locked, and, moreover, there

Digitized by Google

is reason to suppose that, either by the use of some instrument or by temporary removal or displacement of a portion of the partition woodwork, the key on the room side of the lock could be reached. It is matter of the highest importance that the authorities should satisfactorily explain the position in which Lipski was found with a box in front of him, and with his acid-stained coat covered with the coat of the deceased woman's husband, which had previously been hanging in the room. Had Lipski committed the murder and afterwards attempted suicide, one would not have expected to find what to our minds is strong presumptive evidence of foul play practised on Lipski himself, evidence consistent with the convict's story of the occurrence. And, again, assuming that the theory of the prosecution was correct, was it not strange that no sounds were heard by Simon, and possibly by Schmuss, who, according to the statement of the convict's solicitor, were one or both in the house at the time the murder is believed to have been committed? We can conceive that the abrasions on Lipski's elbows may have been caused in more ways than one; but obviously they were more likely to have been inflicted in the manner suggested by the defence—viz., whilst Lipski, lying on his back, was offering resistance to an assailant. It is doubtful if the quantity of acid employed can be more than rudely guessed at, for it is so powerfully corrosive, and causes such obvious stains, that, in common parlance, a little goes a long way. And since the purchaser of the acid cannot be positively identified, can it be expected that much light will be thrown on the case from inquiries directed to this end? We trust Mr. Matthews will base his decision on a general consideration of the whole affair, and not in any way limit himself to the determination of the question of "a life against a bottle." After careful and anxious inquiry, and after balancing the evidence, we unhesitatingly avow that Lipski's guilt has not been proved beyond reasonable doubt. In saying this, we do not desire to cast any aspersion on the jury who tried the case. Their duty must have been a painful one, and their task unusually difficult, for, as the learned judge observed, the case was the most extraordinary he had met with in his judicial experience.

A correspondent, whose opinions on medico-legal questions are entitled to the greatest weight, sends us the following remarks on the medical aspect of Lipski's case:—"The medical aspect of the Lipski case has received much less attention than it deserves. The question which is most, and indeed vitally, important is—Whether the man now under sentence of death could become insensible, or could render himself insensible, under the circumstances reported at the trial and at the preliminary inquiries. Had Lipski been found on the bed upon which the murdered woman lay, or had he been found on the floor of the room between the bed and the floor, or near the window, it might be supposed that he had fallen in syncope, from which he had not rallied at the time he was discovered. But he was found unconscious under the bed, with an egg-box in front of him, and we have therefore to assume that he crept there to faint, or else to render himself insensible by some stupefying agent. The hypothesis is incredible, if not impossible, and as far as I know, has for its foundation not one tittle of medico-legal experience. I have sought in vain for anything in the records of forensic medicine that would lend support to such a view, and in my experience it has nothing that could give it the slightest countenance. Another point is the nature of the insensibility. It was not from syncope. It does not tally with the unconsciousness that would be produced by any known anæsthetic or narcotic. It would, however, be accounted for as due to the effects of a stun by a fall or blow, and belongs, without any doubt, to the condition known as cerebral or cerebro-spinal shock. These circumstances all tend to favour the widespread feeling that the guilt of Lipski is not sufficiently certain to allow the nation, with a clear conscience, to commit the irrevocable act of taking the life of a fellow human being, however dark may be the suspicion which appears to cling to him."

RABIES IN DOGS.

THE report from the Select Committee of the House of Lords on rabies in dogs is decidedly satisfactory. Whilst admitting the value of universal muzzling for a period, say of twelve months, with a view to the extirpation of the disease, the committee thinks that this, to prove of real efficacy, should be supplemented by an almost impossible exclusion of foreign dogs. The committee also considers, and doubtless with good reason, that the seizure, detention, and destruction of stray dogs, and the unusual care which dog owners exercise under pressure, are of no little avail in bringing about a diminution of the disorder. The committee rightly think that it is not within their province to discuss or question the conclusions of the committee appointed by the Local Government Board to inquire into Pasteur's treatment. We sincerely hope, as we have hitherto advocated, that the treatment may, in the words of the report, "be applied not only in Paris but in every place where the need may exist and scientific skill be found." The second paragraph of the report asserts that "it is practically proved that subcutaneous inoculation with its virus is the only ascertained means of imparting the disease, and that in order to check it every effort should be made to prevent the dissemination of the infective substance." This is a careful and well-guarded statement, for it asserts nothing more than the facts fully justify as ascertained by Victor Horsley, Nicols, Fleming, and Brown, whose evidence also went to prove that the disease had not originated spontaneously, though it is admitted that it cannot be absolutely demonstrated that rabies does not arise *de novo*. We are glad to observe also that the report states unreservedly that climatic conditions and special treatment of dogs have no influence in the causation of the affection. Without following the report closely, we may say that its statements and conclusions are quite in accordance with those which are accepted by the best authorities, on whose evidence, indeed, the statements and inferences have been drawn up; and the recommendations of the committee, which we printed last week (p. 336), will meet with the reasoning assent of all who have carefully studied the subject.

THE PECULIAR PEOPLE AGAIN.

JAMES RUSH, a labourer of Steeple, has been sent to prison for a month by the magistrates in petty sessions at Latchingdon, Essex, for neglecting to provide medical attendance for his child, who, after measles, was found to be suffering from ophthalmia and eczema of the face in an aggravated form. In all previous cases where parents have been so charged the patient has died. Here the child still lives, but in much suffering, and—according to Mr. Gorton Coombe, medical officer of health—with the sight of the left eye almost entirely gone. The only defence that Rush made was that "he trusted in the Lord." The magistrates told him that he had treated his child most cruelly and unnaturally, which, of course, he denied. The prosecution was at the instance of the Board of Guardians, whose attention was called to it by Mr. Gorton Coombe, who received information of the case in his capacity as medical officer of health of the Southminster district. The case is a pitiable exhibition of stupidity and ignorance. The medical officer of health would have failed greatly in his duty, and would indeed have been guilty of great inhumanity, had he not exposed the facts and thrown the responsibility of dealing

Digitized by Google

with the parents on the guardians, who in their turn very properly threw it on the magistrates. The result is not a very brilliant one. The father is sent to prison, and the child is left to the care of its mother. She has been urged to allow the child to go to Maldon Workhouse, but she is taking time to think over the matter. It would seem only reasonable that the guardians should quickly give the mother the choice of placing the child under proper medical care or punishing her as they have the father. On religious grounds alone the behaviour of the Peculiar People is absurd, and unmindful of the great Teacher, who said they that are sick have need of a physician; and on humane and social grounds it is clearly right, as it is legal, to see that children have the prime necessaries of life and health supplied to them when their parents fail in their duty. There is a disease known to medical men in which such neglect as this might involve the speedy loss of both eyes, and in which medicine is capable of effecting a quick and complete cure. Will the most ardent champion of parental liberty argue that a parent is at liberty to throw his child into complete blindness on a fanciful and conceited reading of an isolated passage of Scripture? It is the very business of civilisation to curtail such freedom as this, and to bring the peculiarities of the peculiar into decent conformity with the common sense of mankind.

PROFESSOR POTTER (OF SAN FRANCISCO) AND HOMŒOPATHY.

DR. SAMUEL POTTER, Professor of Theory and Practice of Medicine in the Cooper Medical College, San Francisco, author of the "Index of Comparative Therapeutics," to which so much reference has been made by Dr. Brunton's critics, writes a long and able letter to vindicate himself from the charge of having ever practised homœopathy (though he admits having graduated in a homœopathic college), and from other charges equally inaccurate. We do not think that the censure of Dr. Potter's critics needs such lengthened and careful refutation as Dr. Potter gives it. It is enough to notice his chief reasons for abandoning an exclusive system, all that was good in which, he says, was based on Haller's suggestions in his preface to the Swiss Pharmacopœia about 1775, forty years before Hahnemann's pretentious and absurd doctrine had developed. "I abandoned homœopathy," he says, "before entering into practice, because my observation of the reception by homœopaths of Dr. C. Wesselhoeft's reproving of Carbo Vegetabilis, and Dr. Sherman's work on the Milwaukee Test of 1879, proved to me that no crucial drug experimentation conducted under scientific safeguards could meet with any degree of appreciation from the majority of that sect. I was further impressed by finding that ninety-nine out of every hundred so-called homœopathic physicians were in the habit of resorting to regular therapeutics whenever there was any active therapy to be done."

"SLEEPING FOR THIRTEEN MONTHS."

ANOTHER case apparently of hypnotic unconsciousness has been discovered by the newspapers. The patient is a Russian aged forty-three, who has been for thirteen months in a state of unconsciousness in the workhouse at Walton, under the care of Mr. R. McG. Anderson, from whom we learn that the particulars as published are substantially correct, but for this important detail, that the "very remarkable feature of the case" concerning the patient's readiness to take food is a misinterpretation, for liquid food was simply swallowed by the patient in a reflex and unconscious manner. The loss of mental activity appeared to have resulted from the effects of the hot weather in July, 1886, and it is certainly possible that the "sleep" may have been excited by this cause, but it would be necessary to suppose also that a certain predisposition to loss of consciousness must have formed a part of the man's constitution. As far as we have been able to gather from the record of the case, there seems to be no reason to doubt the diagnosis of this case as being a genuine one of hypnotic sleep, not induced by drugs, or by any tangible morbid state of the blood or nervous centres, but best defined, in the present state of our knowledge, as a peculiar functional disturbance of the grey matter of the cerebral cortex, possibly akin to that which occurs in ordinary sleep, and probably affecting a very large area of the perceptive and sensory centres of the cerebral hemispheres. Comparing the healthy brain for the moment to magnetised iron, we may look on this hypnotic state as iron which has been demagnetised by some slight but efficient cause.

THE PROPOSED NEW UNIVERSITY.

IN the House of Commons on the 12th inst., in answer to a question from Mr. Bryce, Mr. W. H. Smith said that no petition had been presented to the Queen in Council from the Royal College of Physicians of London or the Royal College of Surgeons of England asking for a Charter for a representative body of those Colleges to examine for and confer medical degrees. Caveats had been received in regard to such a Charter from various quarters and from five of the Universities. A petition to Her Majesty in Council had, Mr. Smith stated, been received from University College and King's College, London, conjointly, and also from the Association for promoting a Teaching University for London, in favour of a new University for the London district. The grant of the Charter was opposed by the London Univerasity. The petitions were submitted to the Queen in Council on July 12th, and were referred by Her Majesty to a committee of the Lords of the Council to consider and report thereon. It is competent, said the right hon. gentleman, for any persons or bodies interested to petition Her Majesty in Council at any time before Sept. 1st, and subsequently the whole question will be considered by the committee.

THE EARLY SIGNS OF LOCOMOTOR ATAXY.

Dr. MAX KARGER has published as a graduation dissertation in the University of Berlin an account of a number of observations made on 117 cases of locomotor ataxy in Professor Mendel's clinic, with the view of detecting the early symptoms of this disease; for, as he says, the great hope of a really rational and satisfactory method of treatment lies in the recognition of the existence of the disease in its earliest stages. The history given by the patients established a connexion between syphilis and locomotor ataxy in 53 per cent. of the cases. In the earlier stages he found symptoms affecting sensation, lancinating pains, numbness, especially of the lower extremities, cord-like sensation round the waist, retardation of the rate of conduction of sensations, and, what he looks upon as especially important, being almost always present, the so-called Romberg's symptom—i.e., the inability or great difficulty of balancing the body when the feet are placed parallel and close together, the eyes being shut,—which, however, he does not consider is due to the ataxy, but thinks it is an abnormal condition of sensation. With regard to ophthalmic symptoms, he finds that at the commencement of locomotor ataxy there is a diminution in the acuteness of vision, and a concentric contraction of the field, amblyopia and amaurosis, which were due in 35 per cent. of the cases to atrophy of the optic nerve. Then there were slight and transitory paralyses of the eye muscles. Insensibility of the pupil to light was found in 66 per cent. of the cases, and was due sometimes to a paralysed condition of the sphincter, and sometimes to disturbances of reflex action. With reference to the patellar reflex, the author thinks it has been considered to be absent rather too

Digitized by Google

universally. He found it in eight of his 117 cases. The bladder reflex was often diminished, so that chronic vesical disease, the cause of which is not to be made out, ought to lead a medical man to think of tabes. Impotence was much more common than any increased sexual reflex. Very rarely gastric and cephalic "crises" and joint affections were noted. The author suggests that complaints of a vague nature, such as nervous pains, eye or bladder troubles, should lead the physician to make a thorough examination with special reference to the want of patellar reflex, Romberg's symptom, and the want of reaction of the pupil, as these objective signs do not necessarily give rise to any subjective symptoms.

CHOLERA INTELLIGENCE.

NEWS of cholera in Europe is still limited to Italy and to Malta. So far as the mainland of the kingdom of Italy is concerned, the only news as to the cholera comes from Naples and the neighbouring town of Resina in the bay. As regards Naples the intelligence is very conflicting, but there can be little doubt that true cholera prevails there to some extent. At Resina there was, during the close of last week, a daily record of deaths varying from two to five in number, but since then it is stated that material improvement has taken place. In Sicily the disease is still prevalent in the provinces of Palermo, Messina, and Catania, but apart from Palermo there is a diminution in the number of attacks. In Malta over seventy attacks and forty deaths occurred in the week ending the 15th inst., the daily record of deaths varying from thirteen to two. So far, there is no news of any attack amongst the troops garrisoned in the island. Cholera is also prevailing widely in Northern India; the exceptional prevalence of the disease being attributed to a heavy and continuous rainfall ensuing on drought. On the 15th inst. a telegram was received from Simla to the effect that the medical returns from the North-West Provinces showed that 70,000 persons had died there from cholera during June and July, this being at the rate of 1 per cent. of the population.

SPINAL CURVATURE.

IN a clinical lecture by Dr. Mollière, surgeon to the Hotel Dieu in Lyons, upon the etiology and treatment of curvature of the spine, the causes are divided into three main groups: 1. Affections of the head and neck, including astigmatism, enlarged cervical glands, goitre, contraction of the sterno-mastoid, and hysterical or other paralyses of the muscles of the neck. 2. Affections of the lower extremities, including congenital dislocation of the hip, coxalgia or "growing pains" in the hip, knock-knee, rickets affecting the tibia, fractures with shortening, a relaxed state of the foot and other ligaments, and juvenile paralysis. 3. Affections of the vertebræ themselves, or of the thorax, causing true or essential curvature, including pleurisy and excessive exercise of the muscles of one side—such, for example, as existed among the early pressmen, who are represented in old caricatures with a hump near the left shoulder. In addition to these causes, it must be confessed that in a large number of instances there are others which cannot so satisfactorily be made out. Dr. Mollière has given a good deal of attention to this subject, studying the thoracic functions of hunchbacks and examining such muscular theories as appeared to present any hope of a solution of the question. Is, he asks, curvature caused by paralysis of the muscles on the opposite side, as is supposed by some writers? Post-mortem examinations of hunch-backed women negatived this theory, as no muscular or nervous lesion could be found, and no compression of vessels or nerves in the vertebral foramina. Again, is curvature due to muscular contraction on the affected side? Still less is this the case, for the electrical conditions of the muscles and the want of success in the divisions of muscular tissue proposed by M. Guérin both show the incorrectness of this theory. In order to elucidate the subject, M. Mollière some years ago divided three of the intercostal nerves of one side in a young rabbit close to the foramina, reuniting them immediately. The rabbit became hunchbacked, the curvature being on the side operated upon. The animal was allowed to grow up, and was then killed and examined. No trace of the operation could be discovered, the cicatrisation of the nerves being perfect, and no muscular or nervous lesion being discoverable. This experiment proves, according to M. Mollière, that true curvature of the spine is due to temporary paralyses of the intercostal muscles during youth. These paralyses pass away, but the curvature which is produced on the paralysed side remains. In these cases the hope of cure lies in a rational system of gymnastics; but if the curvature is very great, a jacket should be applied while the patient is in a hanging posture.

"STOOPING FORWARDS."

EVERYONE knows that stooping forwards, particularly after rising quickly from bed in the morning, when the stomach is empty and the heart has less than ordinary support from the viscera below the diaphragm, is very apt to occasion a form of faintness with vertigo not unlike that which occurs in sea-sickness. We do not at the moment speak of the faintness and giddiness from cerebral anæmia, which are directly consequent upon suddenly assuming the erect, after long continuing in the recumbent, posture; but of the more alarming sensation of being in the centre of objects which are rapidly passing away, usually from left to right, with loss of power to stand or even sit, and an almost "nightmare" feeling of inability to call for help or do anything to avert a catastrophe, while throughout the experience the sufferer retains painfully acute consciousness. This, we say, is familiar as one at least of the effects not uncommonly produced by stooping forwards under the special conditions indicated. With many other varieties of the vertigo consequent upon heart weakness or cerebral anæmia observation or experience has made us all acquainted. We cannot, however, help thinking that the consequences of even partial compression of the veins of the neck, offering an obstacle to the return of blood from the head, with its important organs, are not so well recognised. The peculiar form—or, more accurately, the several forms—of headache distinctly caused in this way when the head is long bowed forward on the chest, bending the neck on itself, cannot fail to occur to everyone; nor will the high tension of the eyeball, the turgid and heavy eyelids, the snuffling nose, the deafness, with buzzing or throbbing in the ears, the heavy breathing, and the puffed and perhaps flushed or darkened colour of the face, resulting from the obstructed venous circulation through the bended neck, be forgotten. There are other and more perilous, though secondary, effects of leaning forwards when the heart is weak, or the bloodvessels are not so strong as they ought to be, which should not be overlooked. Beyond question the extra strain thrown upon the apparatus of the circulation by anything that impedes the free passage of blood through almost any part of the venous system is more severe and dangerous than a *physically* equal strain thrown on the arteries. At least, this is so in adult life, and, without going further into details in connexion with the *modus operandi* of the mischief to which we point, it may be permissible to urge that the subject is one to which attention may be usefully directed. The weakly, and those who are not unlikely to have hearts readily overburdened, and bloodvessels easily stretched beyond recovery,

Digitized by Google

or even ruptured, should be warned quite as earnestly against suddenly assuming, or too long retaining, postures which do—however slightly and partially—impede the return of blood through the veins. We know how prolonged sitting may cause the veins of the legs to become distended, and either give way or permit the extravasation of their contents. When this sort of thing happens, even though in comparatively trifling degree, in the case of vessels directly connected with such delicate organs as the eye, the ear, and the brain, it is easy to see that the results may be very serious in their character; and, probably, few postures commonly taken up by persons who lead somewhat sedentary lives are so prone to do mischief unnoticed as that of "leaning forwards," as at work at a table which is not sufficiently high to ensure the head being so raised that the veins of the neck may not be in any way compressed or the return of blood from the head embarrassed or delayed. We see reason to believe that if this apparently small matter were more generally understood there would be fewer head and heart troubles, and we will go so far as to say that some lives now lost would be saved.

REFLEX AUDITORY NEUROSES.

THE changes at a distance from the site of irritation when this is about the organ of hearing are of great interest, though of doubtful interpretation. Schmiegelow has given renewed attention to them, and rightly points out some fallacies which Urbantschitsch seems to have overlooked, more especially in connexion with the alleged diminution of the acuity of vision on the same side of the body as the aural disease. Even in 1838 Delau recorded two cases of suppurative inflammation of the tympanic cavity, in which the sight of the corresponding eye was lessened whilst the ear was diseased, but improved as the ear got better. The phenomenon is not due to propagation of the inflammation to the retina, for the optic disc presented no pathological change. Schmiegelow doubts the accuracy of Urbantschitsch's observations, in which too much importance was attached to insignificant ameliorations of sight, and enough account was not made of the size of the pupils and of variations in refraction. Another unsettled question is the alleged reciprocity between the two ears, of such a kind that a loss of hearing on one side appears to give rise to a slight diminution of auditory powers on the other side. Besides various forms of neuralgia and the well-known vertigo, many mental symptoms, and even forced movements, have been ascribed to affections of the middle ear, but it is not improbable that damage to the more elaborated structure of the labyrinth may be operative in the production of some of these symptoms.

"SUSPICIOUS" DISEASE IN SPAIN.

THE only fresh explanation that appears to be forthcoming as to the cause of the outbreak to which we referred in our issue of the 6th inst. is a communication to a medical journal from a practitioner, who says that a member of his family who had been drinking goat's milk, having colic, he tested the goat's milk and found traces of corrosive sublimate in it, a circumstance which he believes is due to shepherds using a wash of this substance for their flocks for the purpose of destroying the larvæ of a fly which deposits its eggs in the cracks of goats' teats. The same correspondent remarks that he found corrosive sublimate in some cheese which had been sent to him from Seville a short time before, and which had produced "colic" in four persons who had partaken of it. The shepherds, whom he says he has often seen in his youthful days applying what they call *solfman* to the animals' teats, have no idea of the poisonous nature of the substance. The fly deposits its eggs in the summer only, and that is why these suspicious "colics" occur to those who partake of goat's milk and fresh cheese in the hot weather only. Some "suspicious cases" have been reported at Torrijos and Alhama, those in the latter locality having been diagnosed as sporadic cholera.

INFECTIOUS DISEASE IN LONDON.

SCARLET FEVER still continues to increase in London, as many as 217 cases having been admitted into the hospitals of the Metropolitan Asylums Board during the fortnight ending Friday last, leaving on that day 640 cases under treatment. The patients appear to have been received from all parts of the metropolis, Hampstead excepted. In this district the North-Western Hospital has been opened for the reception of persons suffering from scarlet fever, and ten cases had been admitted during the fortnight, leaving twenty-three under treatment in this institution. Of other fevers, there were but sixty-six cases remaining in the hospitals of the managers, of which fifty-six were of enteric fever and one of typhus. London still remains free from small-pox, but one patient suffering from this disease having been admitted during this period. Application has been made for the admission of a patient suffering from "cholera," but the Asylums Board were compelled to refuse the case, for the reason that no arrangements had been made for the reception of such cases, or could be made without the sanction of the Local Government Board.

THE ART OF BATHING.

THE bathing season of this year has thus far proved not less, perhaps more, fruitful of fatalities than usual, and visitors to the seaside cannot be too earnestly cautioned to avail themselves of all the local knowledge that is to be had before committing themselves to the movements of the tide upon what may be treacherous stretches of coast. Many a good swimmer has already this season found cause to regret the very proficiency which made him heedless of such an obvious peril as the outflowing of the tide. In most watering-places, however, there is no difficulty in getting ample security in this respect. Sea-bathing is an exercise for which more or less complete provision is made, after a fashion, at all the favourite resorts along our coast. That fashion, however, leaves very much to be desired. The familiar bathing machine is commonly a screen, and nothing more. The floor and seats will probably assume in use such an angle to the horizontal as makes it impossible either to sit or stand with comfort. The wooden roof shuts out the sunshine, depriving the bather of both light and heat. The cramped space affords no sufficient room even for the mere use of towels, and puts everything in the nature of athletic or calisthenic exercise wholly out of the question. The confined air, instantly saturated with moisture, throws the whole duty of drying the damp surface of the body upon a pair of clammy towels. The oozy floor keeps the feet wet and cold; while, finally, the isolation of this dismal cell converts what ought to be the most enjoyable part of the bathing operation into a brief term of solitary confinement. Such are some of the defects in our appliances. It cannot be surprising if, associated with these crude contrivances, there are some very faulty methods. Perhaps there is no error more common than that of over-long immersion. The error is, indeed, a most natural one. The bather has probably waited an hour to secure a "machine." He has the assured prospect of spending a most unhappy half-hour in it when the immersion is over, and it seems a very incommensurate advantage to be paddling about in the water for five minutes. Yet for the great majority of bathers five minutes' immersion is quite long enough. Especially is this so with a bather who does not swim. In his case immersion means partial

Digitized by Google

immersion only. He stands with shoulders, chest, and back exposed to the air, and offering a large evaporating surface from which heat is abstracted much more rapidly than from the submerged area, and by conduction through the insolated surface water of the sea. If to this be added the important fact that such a position is usually a very unaccustomed one to such a bather, we have a set of conditions in which it is plain that great circumspection should be used and the strictest moderation of indulgence must be prescribed. The swimmer even, whose familiarity with the water indicates, among other things, that he has had many opportunities of judging how long immersion suits his constitution, very commonly errs by exceeding the fifteen or twenty minutes which a wise discretion would prescribe.

FREDERICQ ON THE RESPIRATORY MOVEMENTS.

M. FREDERICQ, Professor of Physiology in the University of Liège, has communicated to the Belgian Academy of Sciences some interesting experiments he has just made on the regulation of the movements of respiration. He took two large rabbits, and, having anæsthetised them, cut the right carotids and connected the cardiac extremity in each with the cephalic extremity of the other rabbit by means of tubes filled with a 0·6 per cent. solution of chloride of sodium. He then tied the left carotids and the two vertebral arteries in both, the head of each rabbit being thus supplied exclusively with blood from the left ventricle of the other. He then attempted to cause dyspnœa in one of the animals by obstructing the trachea, and by administering air highly charged with carbonic acid. Difficulty in breathing, showing itself by deep and rapid respirations tending to pass into convulsions, was produced as under similar conditions in ordinary circumstances, but not on the rabbit subjected to the treatment. In that animal the respirations went on as before, while the symptoms of dyspnœa were confined to the other animal. The respiratory centre in the medulla of the rabbit whose trachea was compressed, being supplied with fully arterialised blood from the other rabbit's heart, entirely ignored the venous condition of the blood in the major part of its own arterial system; while the respiratory centre of the rabbit whose respiration was unobstructed, being supplied with highly carbonised blood, and being stimulated to abnormal activity thereby, immediately communicated exaggerated movements to the respiratory functions under its control.

THE DEGENERATION OF THE TEETH.

AN article recently published in an evening contemporary very properly criticises the theory started in an American dental journal that vegetarian diet would, if universally adopted, produce an edentulous condition of the jaws in the course of a few generations, utterly regardless of the fact that vegetarian races have magnificent teeth. The pathology of this condition is stated to be *disuse* and consequent atrophy of muscles and jaws, then degeneration, and ultimately suppression of the teeth entirely. That comparatively little employment of teeth has something to do with their degeneration in civilised nations admits of no doubt; but how many thousand years must it take to make man edentulous, when there are so few evidences of a tendency in that direction. The wisdom teeth are said to be disappearing because they are so often ill-developed and frequently never erupted, and the same remark may sometimes be applied to the upper lateral incisors; but many Egyptian mummies and Etruscan skulls two thousand years of age exhibit the same conditions, yet there is no race of men edentulous. "Are the teeth of the present century worse than those of the last?" is a question by no means easily answered, for we have only general observations and no statistics to go by. Dental surgery is a modern art, and too much separated from its parents—medicine and surgery—to satisfactorily decide the question. Moreover, dentists only see those people who have defective teeth. Again, much more importance is attached to teeth than in former days, and they consequently receive more attention. It has often been pointed out that the vast improvements in medical and surgical treatment serve to keep alive a large number of weaklings who would otherwise have died, and these often have a progeny of similar frailty, whose teeth we may legitimately conclude partake of the general infirmity. On the other hand, dental disease, if early treated, as is now done, may be to a great extent stamped out. Of course, the teeth of civilised nations are worse than those of savages, although, as has been remarked in our columns, those of the latter are by no means free from disease.

RUPTURE OF THE PERINEUM: GIBSON AND WIFE v. JEFFRIES AND HILLS.

THIS case was tried at the Guildford Assizes, before Mr. Justice Cave, on July 21st, in which damages were sought to be recovered for alleged negligence and unskilfulness on the part of the defendants, in the treatment of the plaintiff's wife in her confinement. In the treatment the use of the forceps was required, and, the patient being a primipara, the employment of the instrument resulted, it appeared, in the rupture of the perineum. The rupture extended into the rectum. The verdict was for the defendants, but the jury were of opinion that there was not sufficient medical supervision over the nurse in the after treatment. The trial was a fair one, and the judge's summing up was very discriminating. But it is a pity that the action was ever commenced. Several medical witnesses testified that they had repeatedly got valuable and patient assistance from Mr. Hills in bad midwifery cases, and Dr. Grafly Hewitt—who was requested to examine the patient and report on her by Mr. Chapman, who took charge of the case a few days after delivery,—after careful examination of the facts and of the case, expressed the opinion that there was no evidence to sustain a charge of malpractice. He said that perineal rupture sometimes happened in the most skilful hands. One point on which Dr. Hewitt's opinion was asked was whether the hand of an assistant would have saved the perineum; he replied that it would not. He said the avoidance of laceration depended for the most part on the skilful manipulation of the forceps. In regard to guarding the perineum, we are of opinion that, whenever practicable, a second surgeon should be retained to make this object his special care. But such actions as the one referred to are unreasonable. Those who are most experienced in midwifery will most mercifully judge accidents of the kind which occurred in the above case.

CARELESS LABELLING OF BOTTLES.

AT the Lewes Assizes last week, before Mr. Justice Grove and a special jury, an action was brought against a well-known firm of pharmaceutical chemists for carelessness in labelling two bottles, one containing blistering fluid for application behind the ears, the other a collyrium. The medicines were rightly made up, but the labels were put on wrongly. This was explained by the statement that the "finisher"—the person who labels the bottles—made the mistake. The defendants, without acknowledging liability, had paid £50 into court. Mr. Critchett gave evidence that the patient was suffering now from gouty inflammation of the eye, and that the accident had done her no substantial harm. The jury awarded the plaintiff £62 damages, being £12 in addition to the £50 paid into court. The judge took occasion to express his regret that directions in pre-

Digitized by Google

scriptions were not written in English, and gave a striking instance from his personal experience in which a mistake was made by the dispenser that might have been fatal but for the patient's knowledge of Latin. There is much to be said for this, though it is not very relevant to the case, where the labels were rightly written but placed on the wrong bottles. It seems more to the purpose to insist that the person who makes up the medicines shall affix the labels.

GLASGOW ROYAL INFIRMARY AND THE UNIVERSITY.

A DEPUTATION, representing the directors of the Glasgow Royal Infirmary and the Merchants' House, had an interview with the Secretary for Scotland on the 9th inst., to urge that in the Scotch Universities Bill provision should be made for erecting the medical school in connexion with the Glasgow Royal Infirmary into a college of Glasgow University, in the same way as the College of Dundee was proposed to be affiliated to the University of St. Andrews. The deputation having explained their views, the Marquis of Lothian said that from the fact of a provision of that nature having been in the Bill which was previously brought before Parliament, although not passed, and it having been thought desirable to eliminate it, he should like to have an opportunity of reconsidering the matter in all its bearings. He assured them that the representations of the deputation would have his best consideration. There was, he thought, very little chance of the Bill passing this session, and there would thus be plenty of time to consider the matter.

LIFE-SAVING AT SEA.

THE very short report which has been presented by the Select Committee appointed by the House of Commons "to inquire into the existing laws and regulations" regarding boats, life-buoys, and other life-saving gear, contains many suggestions of such obvious value that one can only feel surprise that they have not been adopted long ago. For instance, "your committee consider that in ships carrying passengers all seats, chairs, stools, lockers, and other movable articles on the deck of such vessels, suitable for flotation, should be sufficiently buoyant to be capable of supporting one or more persons in an emergency." This seems to be the very A B C of prudence, but it probably will never make due impression upon the builders and furnishers of ships until it has been imposed upon them as a regulation by the Board of Trade. It does not appear, however, that the Legislature is itself free altogether from the charge of having overlooked some most obvious considerations when prescribing the kind and quantity of life-saving apparatus which a ship shall carry. Thus the committee remark:—

"With reference to boats, the evidence points out the necessity for having new regulations affecting them. The existing law does not compel any passenger ship over 1500 tons to carry more than seven boats, while in cargo vessels the boats are often considerably over the number which could possibly be useful to the crew on an emergency. Your committee think that boats of all vessels of over 100 tons' register, should be inspected at certain stated intervals, be lowered into the water and examined as to whether they are watertight, and whether the falls, davits, and all gear connected with the boats are in a thoroughly trustworthy and efficient condition. Your committee find that many passenger ships could not, without great inconvenience, carry so many of the ordinary wooden boats as would suffice to carry the whole of the passengers and crew with safety in bad weather. Under such circumstances the crew would not be sufficient to man so many boats; nor could they all be got into the water in sufficient time in the event of very rapid foundering. Having regard, however, to the fact that accidents occur probably as often in moderate weather as in bad, and having regard also to the fact that the very cause of the accident frequently incapacitates many of the boats, and to the further fact that an insufficiency of boats undoubtedly tends to cause panic, we are of opinion that all sea-going passenger ships should be compelled by law to carry such boats, and other life-saving apparatus, as would in the aggregate best provide for the safety of all on board in moderate weather."

Valuable as these suggestions are, we think that the suggestion with which the report concludes is more valuable still. The committee recommend the appointment of a permanent committee on which all the parties interested in navigation would be represented to keep this whole subject under observation, and frame rules from time to time. Only thus will it be possible to take advantage of the latest developments of science which, by its steady advance, is constantly rendering antiquated the unrevised regulations which represent the wisdom and knowledge of an earlier decade.

POOR-LAW MEDICAL ASSOCIATION.

WE regret to have to announce that Mr. John Wickham Barnes, who has been for some years the active and indefatigable secretary of the Poor-law Medical Officers' Association, and who has been somewhat out of health of late, has had a severe attack of choleraic diarrhœa, which almost assumed an Asiatic type. It would appear that he was taken suddenly ill at Wimborne, whither he had gone on business. He is now convalescent and on a fair way to recovery. We are pleased to be able to announce that Dr. Joseph Rogers, who has been staying for some weeks at Herne Bay, has so much benefited by his visit there that there is every probability, in the opinion of his medical advisers, that he will be enabled to resume his work in the interests of the Poor-law Medical Service, which has been in abeyance for some months past.

KAKKE OR BERI-BERI.

THE etiology of this strange affection being confessedly obscure, all attempts to throw light upon it should be well considered. There is no need to refer to the articles on Japanese kakké which have so recently appeared in our columns, further than to remark that the cause of the disease appears to exist in water or food, and can affect human beings and some animals by being swallowed. A Dutch physician from Atchin reports in the *Weekblad van het Nederlandsch Tijdschrift voor Geneeskunde* of June 18th that an epidemic occurred about a month after the ground in a certain locality had been flooded, and that after antiseptic measures had been taken and the neighbourhood well disinfected the disease was arrested. This, he suggests, points to the existence in the ground of the cause of the disease, the incubation stage of beri-beri being, as he says, long—probably about four weeks. No attention seems to have been directed by oriental observers to the very interesting observations of Dr. Lacerda of Rio de Janeiro, who in 1885 published a pamphlet, which is now before us, entitled "Peste de Cadeiras, ou Epizootia de Marajó; suas Analogias com o Beri-beri" (Hip Epidemic, or Marajó Epizootic; its Analogies with Beri-beri), in which he gives an account of a fatal disease affecting horses and swine in the island of Marajó, which appeared to be due to a polymorphous microphyte belonging to the Ascomycetes, which abounded in the water of Lake Arary in the island. This microphyte was found to produce the disease in a number of animals, rabbits, pigs, birds, monkeys, &c., inoculated with it. The symptoms and the lesions found in the spinal cord after death corresponded very closely, in Dr. Lacerda's opinion, with those due to beri-beri, and he came to the

Digitized by Google

conclusion that the Marajó epizoötic was identical with that disease. If so, his researches throw considerable light on its etiology, and are certainly well worth the study of those interested in the subject. The pamphlet, which is in Portuguese, has not, so far as we are aware, been translated. It contains, however, several drawings, which are easily understood. A short notice of the work appeared in THE LANCET of Feb. 13th, 1886.

PRECAUTIONS AGAINST DIARRHŒA AND CHOLERA.

IN view of the special dangers from diarhœa and allied diseases at this time of the year, Dr. Tatham, medical officer of health for Salford, has issued a series of instructions for the guidance of the inhabitants of his district. The memorandum embodying them lays down the principle that these diseases are intimately associated with conditions of filth which favour their propagation, and then it proceeds to explain what are the special duties of householders in the removal of all conditions which favour diarrhœal affections, and what steps have been organised by the sanitary authority so as to facilitate cleanliness in and about households. The importance of the early control of symptoms of diarrhœa are referred to, and it is announced that free distribution of diarrhœa mixtures will be given, under proper control, should the occasion arise. Much that is contained in this memorandum deserves the attention of sanitary authorities generally.

PROGRESSIVE SPASTIC ATAXIA.

THE multiplication of names for one and the same disease of the spinal cord or any other organ of the body is not desirable in itself, nor do we think it tends to improve our knowledge of any disease. "Ataxic paraplegia," described last year in THE LANCET by Dr. Gowers, is another name for the affection termed spastic ataxia in a paper in the July number of the *Medical Record* by Dr. Dana. From the latter's point of view the use of some word indicating spasm would seem to be necessary, for he believes that marked weakness of the legs is not common in the disease in question. We do not subscribe to this opinion, for our experience is that constant spasm of legs never exists without considerable impairment of volitional power over them. Dr. Dana's paper is illustrated by coloured diagrams showing the distribution of the combined sclerosis of the lateral and posterior columns.

NEW VOLTAIC COMBINATIONS.

DR. C. R. ALDER WRIGHT, F.R.S., and Mr. C. Thompson, both of St. Mary's Hospital Medical School, have contributed to the Chemical Society some preliminary experiments on batteries, in which the electro-positive metal zinc is replaced by solutions capable of oxidation. The ordinary porous cell arrangement is used, and similar plates of carbon or platinum. The plate of lower potential—that is, the electro-positive plate or the plate replacing zinc—is immersed in the reducing, and the other plate in the oxidising, solution. Steady currents are thereby produced, the energy of which will shortly be determined. Among the couples which have already been tried are the following. In each case we place the electro-positive first. 1. Sulphurous acid against chromic liquor (potassium dichromate and sulphuric acid), sulphuric acid and chromic sulphate being formed. 2. Sodium sulphite against alkaline potassium permanganate. Here sodium sulphate and hydrated manganese dioxide are formed. 3. Chromic hydrate dissolved in caustic soda against chromic liquor. Here sodium chromate is formed in one cell and chromic sulphate in the other. This is a particularly interesting reaction, as the chromium in one cell is oxidised, while that in the other is reduced. By intermediate treatment the action of the cells might be made reversible. 4. Solution of potassium ferrocyanide opposed to chromic liquor. The ferrocyanide becomes ferricyanide according to the following equation: $6K_4FeCy_6+2CrO_3+6H_2SO_4=6K_3FeCy_6+3K_2SO_4+6H_2O+Cr_2(SO_4)_3$. 5. Solution of lead oxide in caustic soda against alkaline permanganate, hypochlorite or hypobromite. Here the lead monoxide becomes peroxide, which deposits in a solid form. It is evident that an almost infinite number of such combinations are possible, and we shall await with great interest the determination of their electromotive force.

TRAUMATIC TETANUS TREATED BY CHLORAL AND BROMIDE.

DR. MAYER relates, in the *Allgemeine Medicinische Central Zeitung*, a very pronounced case of traumatic tetanus, which he treated successfully by fifteen-grain doses of chloral hydrate and bromide of potassium, given alternately every hour for fourteen days. By that time the opisthotonos had ceased, but some rigidity of the muscles of the chin still remained. The chloral was then discontinued, the bromide being given as before for a month longer. The patient was then cured, but was too weak to resume his employment till six months later.

THE INTERNATIONAL CONGRESS ON CREMATION.

FROM Milan a correspondent writes:—The Congress, at which cremation, in its many-sided aspects, was to have been discussed here in September, has been postponed till April, 1888, in compliance with representations addressed to the organising committee by physicians and hygienists, whose presence at next month's Medical and Sanitary Congresses both in Europe and America would have made attendance at its sittings impossible.

THE RESPIRATION IN PARALYTIC RABIES.

AN account of some careful observations on the respiratory rhythm of rabbits suffering from artificially induced rabies is given by Dr. Ferré in the *Journal de Médecine de Bordeaux*, No. 1 (Aug. 6th). The graphic tracings show very clearly the gradual change in type of the respiratory rhythm, which is normally composed of short rapid waves, as seen in the tracing; the respirations become slower and deeper, so that just before death they are six times less frequent than during health. Ferré proves that the first phenomenon of rabic infection is a distinct slowing of the respiration.

TYPHOID FEVER AT MOUNTAIN ASH.

A SEVERE epidemic of typhoid fever is prevailing at Mountain Ash, upwards of 100 cases having already occurred. Unfortunately the actual cause of the outbreak has not yet been clearly determined, although it is believed to be associated with the excessive drought which has prevailed.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Aràmyi von Hunyadvur, Emeritàs Professor of Pathological Anatomy in Pesth, at the age of 78. —Dr. Sheremetevski, of Moscow, librarian of the Russian Medical Society.

IT is gratifying to be able to announce the conspicuous success of the candidature of George Thomson, M.D., C.M. Aber., for the Coronership of the borough of Oldham. There were ten applicants for the post, seven of them belonging to the legal profession.

THE *London Gazette* of the 12th inst. contains a letter from Captain Woodford, R.N., to the Secretary of the Admiralty in reference to the capture of an Arab dhow and fifty-three slaves by Lieutenant F. F. Fegen at Pemba on May 30th, in which the following passage occurs:—"Surgeon W. H. Norman, of H.M.S. *Reindeer*, deserves great credit for skilful surgery under trying circumstances."

THE Balfour Studentship in the University of Cambridge for original biological inquiry will be vacant in October. The value of the studentship, which is tenable for three years, is £200, and the person elected need not be a member of the University, nor is the award made after a competitive examination.

ON the 12th inst. the Queen conferred the honour of Knighthood upon, amongst others, Mr. George Macleod (Surgeon-in-Ordinary in Scotland) and Dr. William Aitken (Professor of Pathology at Netley Hospital). In the previous week a similar honour was conferred upon Dr. Alfred Baring Garrod.

GREAT excitement was caused in Berlin on Saturday, the 13th inst., by the announcement that Professor Virchow had been rejected as candidate for the post of Rector of Berlin University owing to his Liberal political opinions.

DR. POTAIN was summoned in consultation to M. Katkoff, who resided at Snamenskojè, near Moscow, remaining with the great journalist two days. His fee was 20,000 francs (£800).

M. DASTRE, Docteur ès Sciences, Paris, has been appointed Professor of Physiology in the Faculty of Science.

VON PETTENKOFER'S LATEST VIEWS ON CHOLERA.

(*Concluded from page 340.*)

THE impunity with which the ticket-of-leave men before mentioned were transported to other localities justifies von Pettenkofer in the conclusion that, during war, detachments of troops and prisoners can quite safely be sent from a cholera-stricken region to one yet unvisited by the malady, always with the proviso that, like the above-mentioned ticket-of-leave men, the troops and prisoners have been thoroughly cleansed, with all the articles they take with them. In proof of this he appeals to the history of the Franco-German war (1870-71), when, indeed, cholera did not prevail, but when abdominal typhus and dysentery were rife—maladies which have a strong family likeness to cholera in their mode of diffusion and in their dependence on conditions of place and season. The sixth volume of the medico-military report of that campaign warrants Dr. Port in saying that of "the 74,000 typhus and 39,000 dysenteric cases occurring in the German army from the middle of July, 1870, to the end of June, 1871, great masses were continually sent back to the frontier *en route* to all parts of Germany, but that the result was favourable beyond all precedent. Spread of the maladies among the civil population of the Fatherland there was none—a fact which stands in the sharpest contrast to the experience of small-pox in the same year, and to that of spotted typhus in previous campaigns."

In the eighth section, von Pettenkofer enters into the practical question as to the prohibition or permission of fairs and other periodical assemblies of great masses of people during cholera time; and adduces striking evidence from the experience of Nürnberg in 1854 and Leipsig in 1866 in support of his doctrine that "such assemblies in places where cholera is already epidemic are always to be postponed—not, indeed, in the interest of the residents, but only in the interest of the arrivals from elsewhere who may be infected in cholera localities; so long, however, as a place is not epidemically attacked, or has no reason to apprehend, during the time when the popular gathering takes place, that it may be attacked, the people may unreservedly be allowed to meet."

In the ninth section he treats of restriction of communication during cholera time, in the case of barracks and schools. Much, he thinks, "cannot be done in this direction, the question mainly turning on this: "whether or not the barrack or the schoolhouse is a focus of infection. Schools are, so far, of less importance, as residence in them is of short duration, and the schoolboy age is, besides, least liable to choleraic attack. Barracks may be managed, according to their situation, in very different ways, some being exempt from the infection," others being preserves of it, and accordingly to be regarded and treated essentially, as are other houses in the locality. Recruits have more to suffer, as a rule, than their older comrades, and it should therefore be recommended during an epidemic not to call them in, except to barracks which are proved to be cholera-exempt.

As to the circulation of the cholera-dead in funerals and other modes of removal, von Pettenkofer, under Section 10, maintains that the bodies of the deceased from cholera are just as little infectious as the living cholera patient, and restricts himself to a few precautions of special import in cholera localities. The surveillance of the rag trade in cholera time, which the contagionist school lays particular stress upon, he holds to be of little importance, and gives his reason for the same partially under Section 11, but more fully in the final section. Section 12 deals with the subject of cholera linen and other articles coming from cholera localities. In this case von Pettenkofer admits a certain utility in disinfection, according to the bacteriological principles of Koch and Wolffhügel, though he places much smaller value on it than is usually done. Disinfection of dwelling-houses calls for a very simple procedure in his view; but to this, as to all restrictions of communication, isolation of the sick, and disinfection of their evacuations, he attaches very slight importance. He says: "That it does no harm if we neglect all these measures, but act in quite the contrary manner, is strikingly proved in the epidemic which in 1836 prevailed over all Bavaria. The Government had the boldness officially to assure its four million subjects that cholera is not in the slightest degree a contagious disease, but develops itself only from the *genius epidemicus* inhering in localities, in some to a greater, in others to a lesser degree; in some earlier as to time, in others later; that from cholera patients infection never proceeds, and that they may be nursed without fear; that even the cholera stools are quite innocuous—so much so, in fact, that many physicians have not only smelt them, but have even gone so far as to taste them. That during the prevalence of the epidemic in the capital (Munich) more than 40,000 persons had migrated to neighbouring localities, and the disease had thereafter shown itself only in extremely isolated cases. Notwithstanding this manifesto, the cholera epidemic, treated for the first time on anti-contagionist principles, proved the mildest of all that ever visited Munich. According to the contagionist view, this ought to have been the gravest, attacking as it did a population (epidemiologically speaking) quite unseasoned; while every precaution of isolation and of disinfection was neglected, and communication unrestricted throughout the whole country. In spite of this (on contagionist principles) negation of all prudential measures—a line of conduct authoritatively inculcated by the Government on the then small number of contagionistically-minded physicians—cholera, among the four million inhabitants of the kingdom, diffused itself scarcely at all! That was indeed a high-handed epidemiological experiment on the part of the Bavarian Government; an anti-contagionist experiment to boot. It may be said, with human beings you ought to make no experiments involving danger to life or even to health (however much you may vivisect the lower animals). But, as in the case of epidemics, you cannot help doing something, so that which you actually do is called not an experiment, but a 'regulation' to which human beings must conform, just as much as the lower animals are subjected to the conditons imposed by the experimenter. If this great epidemiological experiment practised by the Bavarian Government in 1836 on its four million subjects on anti-contagionist principles had, with the same beneficial results, been made on the

Digitized by Google

principles of the contagionist school, that school would have peremptorily required that its principles should be recognised as the sound ones, just as if the experiment had been practised on four million mice or guinea-pigs. But as this experiment succeeded when applied to men on anti-contagionist principles, it is held to prove nothing at all!"

In his thirteenth section, von Pettenkofer considers the measures to be adopted against individual predisposition to cholera and the specific medical treatment. He takes his stand essentially on the manifesto issued by the Bavarian Minister of the Interior on Aug. 6th, 1883, and insists on the provision that "the organisation of medical establishments for the examination of cholera cases, real or suspected, and the inspection of diarrhœas in single districts (house-to-house scrutiny), for the first time practised in Munich in 1836, should be systematically proceeded with"—measures which worked so beneficially "that of 5157 cases in which they were enforced only 1264 reached the asphyxial stage, and only 553 died." Again, "among the cases of completely developed cholera about two-thirds (66 per cent.) were officially proved to have neglected the premonitory diarrhœa and to have kept out of the way of prophylactic treatment."

In the fourteenth and last section, von Pettenkofer endeavours to show how, on his theory that cholera, epidemiologically considered, depends on conditions of place and of time, the disease may best be combated at its source. You cannot, he grants to the contagionist, alter the essential character of the soil or introduce different climatic conditions in a cholera locality; but, taking the place as you find it, you may effect changes on it which destroy its power of harbouring and developing the cholera germ. He then gives in considerable detail the sanitary operations which have made Fort William, near Calcutta, and Haidhausen in Bavaria, from being foci of cholera, well nigh cholera-proof. The levelling and draining of the soil, the immediate and effective removal from it of all refuse (animal and vegetable), its constant purification internally as well as superficially, were in both cases followed, not only by the practical disappearances of cholera when the malady continued to infect other localities in their neighbourhood not subjected to the same sanitary treatment, but also by the disappearance, in Haidhausen particularly, of contagious diseases of other and hardly less deadly kinds. These measures, carried out coincidently with the proper management of the person on the part of each individual member of the community, are, in von Pettenkofer's view, the one sound and infallible prophylactic against cholera, and supersede the necessity of the elaborate, costly, and vexatious restrictions imposed on society by the contagionist school.

The brief indication of his doctrine which we have given will have fully served its purpose if it sends the reader to the papers themselves from which it has been extracted and condensed—papers which have evoked immense interest in sanitary circles on the Continent, and which in a popularised form are being worked down for the practical instruction of the lay public.

LUNACY IN SCOTLAND.

THE report just issued by the Scotch Lunacy Commissioners, while representing actually a very favourable condition of things, is hardly so promising for the future as that which the English Commissioners were recently able to put forth. The most salient and happiest feature of the English report was that the proportion of lunatics to the general population has fallen slightly within the past two years. The same thing cannot be said of lunacy in Scotland. The proportion (279 per 100,000) which appears in this report is exactly equal to that of last year, and greater than that of any previous year in the Commissioners' review. One consideration does indeed afford satisfaction. Though the percentage of it does not show the same tendency as the English percentage towards diminution, it is at least actually less by a minute fraction; less, that is, in the proportion of 279 to 280. The Commissioners adopt the explanation that the increasing proportion of lunatics under their cognisance "does not necessarily indicate any increasing amount of mental disease, and that it is probably due in a large measure to what is only an increasing readiness to place persons more or less disordered in mind as lunatics in establishments.

As to treatment, the present report may be regarded as upon the whole very satisfactory. The highly important point of finding suitable occupation for the insane receives due attention, and although this aspect of the year's experience is not exhibited statistically with quite as much fulness as we could wish, there are one or two references to it in the report of a highly instructive and eminently satisfactory character. We have already remarked, in reviewing the English report, upon the special difficulty which arises from the unwise susceptibilities of relatives in the case of private patients. The great advantage of giving to the medical man an entirely free hand in this respect is incidentally, and because incidentally the more strikingly, illustrated by the Commissioners' report upon the Lunatic Department of the General Prison at Perth. "This establishment," say the Commissioners, "is reported to be in excellent order. The new kitchen and laundry are in operation, and are found to be of great advantage in affording active and useful occupation for the women. The men are largely employed in gardening and other outdoor work. To the industrial occupation of the patients and other rational modes of treatment may fairly be attributed the fact that the reports record no accident, no escape, and no necessity for the use of mechanical restraint."

Another point of treatment to which this report directs especial attention is that of boarding out. Treatment in the ordinary sense of the word there is none in these cases. The lunatic is placed with some family for custody merely, and only when he is not only harmless, but also incurable, in the judgment of his medical advisers. Were it considered possible for treatment to avail anything, he would, of course, be sent to an asylum where skilled advice and the best appliances would be available. Yet, in spite of this very unfavourable prognosis, there is a record of over forty recoveries among about 2300 such patients. Upon this very striking fact Dr. Fraser makes the noteworthy comment: "Some recoveries, however, do take place, partly because the opinion as to their incurability is occasionally wrong, and partly, as I believe, because the condition of some patients, which would be an incurable one if they were left in asylums, becomes a curable condition under the circumstances which attend life in a private dwelling." We quite agree that, if this opinion is correct, it ought to have an important practical influence on the treatment of the insane, and we shall look with interest for any light which future reports, both of the Scotch and of the English Commissioners, may throw upon this interesting question.

THE VOLUNTEER MEDICAL ASSOCIATION.

WE are glad to be able to record that a serious effort is now being made to thoroughly organise the Volunteer Medical Service of the country under the above title. Some such organisation has long been wanted, and the promoters are to be heartily congratulated upon the success which has attended their efforts. A letter, giving information of the objects of the Association, has been sent to every Volunteer medical officer, the number of whom very nearly approaches 1000. The Association is to be congratulated upon its list of officers and council. We notice the Prince of Wales has given another proof of his interest in the Volunteer movement and ambulance work by accepting the office of president; and amongst the vice-presidents are Sir Andrew Clark, Sir W. Guyer Hunter, Sir James Paget, Sir James Hanbury, Sir William Mac Cormac, Sir William Turner, Sir Douglas Maclagan, Mr. Savory, and Sir Joseph Fayrer. The Council is a thoroughly representative one of the Volunteer Medical Service in every part of the country, and provision is made in the rules for general meetings of the members. The Volunteer Ambulance Department has amalgamated with the Volunteer Medical Association, handing over to its funds a considerable sum of money and valuable material, so that this work will now be carried on under the auspices of the Association. For some time past great dissatisfaction has been felt at the very anomalous position of Volunteer medical officers, the majority of such officers holding the non-commissioned rank of acting-surgeon, and therefore occupying a position inferior to the youngest sub-lieutenant in the service. We are glad to note that in consequence of representations from the Council of the Volunteer Medical

Digitized by Google

Association, these anomalies are to be removed, as will be seen by the reply of the War Secretary to the question put by Sir Guyer Hunter, chairman of the Council of the Association, in the House of Commons. Volunteer medical officers generally, and acting-surgeons in particular, are much indebted to the Council for the interest they have evinced, and we cordially recommend every Volunteer medical officer to join the Association, the offices of which are at 26, King-William-street, Strand.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5844 births and 4191 deaths were registered during the week ending August 13th. The annual rate of mortality in these towns, which had been 23·2 and 22·9 per 1000 in the preceding two weeks, rose again last week to 23·7. During the first six weeks of the current quarter the death-rate in these towns averaged 22·1 per 1000, and was 1·0 above the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 13·2 in Halifax, 15·1 in Huddersfield, 16·3 in Brighton, and 17·2 in Derby. The rates in the other towns ranged upwards to 29·5 in Blackburn, 30·1 in Preston, 30·2 in Newcastle-upon-Tyne, and 31·4 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 1301 and 1292 in the preceding two weeks, further declined last week to 1252; they included 943 from diarrhœa, 104 from whooping-cough, 78 from measles, 57 from scarlet fever, 39 from "fever" (principally enteric), 29 from diphtheria, and 2 from small-pox. These zymotic diseases caused the lowest death-rates last week in Halifax and Huddersfield, and the highest in Birminghom, Salford, Hull, Portsmouth, and Preston. Diarrhœa caused the greatest mortality in Salford, Birmingham, Hull, Leicester, Portsmouth, and Preston; whooping-cough in Sheffield and Birmingham; measles in Newcastle-upon-Tyne, Bolton, Salford, and Manchester; scarlet fever in Birkenhead, Bristol, and Blackburn; and "fever" in Birkenhead. Of the 29 deaths from diphtheria in the twenty-eight towns, 21 occurred in London. Small-pox caused 1 death in Sheffield, 1 in Cardiff, but not one in Greater London, or in any of the twenty-five other large provincial towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan asylum hospitals receiving cases of this disease, of which one was admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding six weeks from 199 to 158, further fell last week to 175, and were 7 below the corrected average. The causes of 6·, or 1·6 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Plymouth, Wolverhampton, Leicester, Nottingham, and in five other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Sunderland, Brighton, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 20·9 to 17·1 per 1000 in the preceding three weeks, rose again to 19·3 in the week ending August 13th; this rate, however, was 4·4 per 1000 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 13·0 and 14·5 in Perth and Paisley, to 24·0 in Dundee, and 26·7 in Greenock. The 482 deaths in the eight towns last week showed an increase of 54 upon the number in the preceding week, and included 37 which were referred to diarrhœa, 28 to whooping-cough, 9 to scarlet fever, 5 to diphtheria, 1 to measles, 1 to "fever" and not one to small-pox; in all, 81 deaths resulted from these principal zymotic diseases, against 103 and 73 in the preceding two weeks. These 81 deaths were equal to an annual rate of 3·2 per 1000, which was as much as 3·9 below the mean rate from the same diseases last week in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 39 and 28 in the preceding two weeks, rose again last week to 37, of which 8 occurred in Glasgow, 8 in Dundee, 7 in Edinburgh, and 5 in Leith. The deaths referred to whooping-cough, which had been 41 and 22 in the previous two weeks, increased last week to 28, and included 8 in Glasgow, 8 in Greenock, 7 in Edinburgh, and 4 in Dundee. The 9 fatal cases of scarlet fever exceeded by 2 the number returned in the preceding week, and included 7 in Dundee. The 5 deaths from diphtheria were within one of the number recorded in the previous week; 3 occurred in Edinburgh. The fatal cases of measles and the death from 'fever" were recorded in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 65 and 67 in the preceding two weeks, further rose last week to 71, and corresponded with the number returned in the same week of last year. The causes of 63, or more than 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 30·9 and 29·6 per 1000 in the preceding two weeks, rose again to 31·5 in the week ending August 13th. During the first six weeks of the current quarter the death-rate in the city averaged 29·4 per 1000, the mean rate during the same period being but 22·7 in London and 19·1 in Edinburgh. The 213 deaths in Dublin last week showed an increase of 13 upon the number returned in the preceding week; they included 27 which were referred to measles, 23 to diarrhœa, 6 to whooping-cough, 2 to "fever" (typhus, enteric, or simple), and not one either to small-pox, scarlet fever, or diphtheria. Thus the deaths resulting from these principal zymotic diseases, which had increased in the preceding four weeks from 45 to 55, further rose last week to 58, and exceeded the number in any week since August, 1884; they were equal to an annual rate of 8·6 per 1000, the rates from the same diseases being 7·0 in London and 3·4 in Edinburgh. The fatal cases of measles, which had been 22 and 16 in the preceding two weeks, rose again last week to 27, and exceeded the number recorded in any recent week. The deaths referred to diarrhœa, which had been 16 and 29 in the previous weeks, declined to 23 last week. The 6 fatal cases of whooping-cough showed an increase of 3 upon the number in the preceding week, while the 2 deaths from fever corresponded with those recorded in the previous week. The deaths of infants and of elderly persons slightly exceeded those returned in the preceding week. Eight inquest cases and 3 deaths from violence were registered; and 52, or one-fourth, of the deaths occurred in public institutions. The causes of 33, or more than 15 per cent., of the deaths registered during the week were uncertified.

THE SERVICES.

Deputy Surgeon-General R. Webb has been appointed Principal Medical Officer, Dublin District.

A Greenwich Hospital Pension of £50 a year for Fleet Surgeons and Staff Surgeons is vacant by the death of Deputy Inspector-General James Vaughan.

INDIA OFFICE.—The Queen has approved of the retirement from the Service of the undermentioned officers of the Indian Military Forces:—Brigade Surgeon Charles Julian Joseph Jackson, M.D., of the Bengal Medical Establishment (dated March 31st, 1887), and Surgeon-Major Richd. Hamilton Batty, of the Bombay Medical Establishment (dated June 24th, 1887). The undermentioned officers have been granted a step of honorary rank on retirement:—Brigade Surgeon Charles Julian Joseph Jackson, M.D., of the Bengal Medical Establishment (dated March 31st, 1887), and Brigade Surgeon Henry Cayley, of the Bengal Medical Establishment (dated April 29th, 1887), to be Deputy Surgeons-General; an Surgeon-Major Richard Hamilton Batty, of the Bombay Medical Establishment (dated June 24th, 1887), to be Brigade Surgeon.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Daniel O'Connor, M.D., has been placed on the retired list, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated Aug. 14th, 1887).

The following appointments have been made:—Fleet Surgeon James Bradly, to the *Malabar;* Surgeon John N. Corbett, to the *Alecto;* and Surgeon John Fogerty, to the *Orwell.*

RIFLE VOLUNTEERS.—5th (Isle of Wight, Princess Beatrice's) Volunteer Battalion, the Hampshire Regiment: Acting Surgeon E. R. Woodford, M.D., resigns his appointment (dated Aug. 13th, 1887).

CATARACT OPERATION IN BRUSSELS.

To the Editors of THE LANCET.

SIRS,—Your annotation on cataract operations as practised by Dr. Coppez leads me to suppose that a brief *résumé* of the subject may not be unacceptable to your readers. Formerly the percentage of loss (fifteen actual, with twenty more or less damaged) from the old flap method of cataract extraction was so great that surgeons, as a rule, declined to operate until the patient was quite blind. On the other hand, iridectomies were constantly practised with scarcely any loss of eyes at all—at most not more than one in five hundred. These contrasted figures set Dr. Schafte, Professor von Graefe's assistant, thinking; and the result of his cogitations was a proposition to perform iridectomy in all cases of cataract, and then remove the lens through the small incision by means of a spoon—an operation which was for a time very generally adopted. It was clear, however, that a slight enlargement of Schafte's incision in the corneo-sclerotic junction would permit of the exit of the lens without the use of any traction instrument whatever, and Graefe's modified linear extraction followed as a matter of course—an operation which, varied by most of the surgeons who adopted it, but always accompanied by excision of the iris, was the method of extraction *par excellence* for twenty years. Despite its great popularity, however, there were numerous objections to von Graefe's method. The incision was too far back; the danger of prolapse of the vitreous was great; a large iridectomy was necessary in order to prevent strangulation of the iris at the angles of the wound; bleeding into the anterior chamber was frequent, and the site of the incision was such as to excite well-grounded fears of sympathetic ophthalmia; and yet surgeons were afraid to bring the incision more forward into true corneal tissue on account of the tendency of this non-vascular membrane to suppurate. This risk is now obviated by the use of antiseptics, and prolapse of the iris, formerly the bugbear of extraction, counteracted by eserine. I introduced some patients who had been operated on by the small corneal flap, with central and movable pupils, to the notice of the members of the Clinical Society of London in 1874, and have within the last three years operated upon 500 patients in the same way. Coppez's incision, which is not precisely the one I adopt, is depicted in the accompanying woodcut, which I extract from a review of his paper in the *Annales d'Oculistique* for June of the present year.

I am, Sirs, your obedient servant,

CHARLES BELL TAYLOR, M.D., F.R.C.S.Ed.,
Surgeon to the Nottingham and Midland Eye Infirmary.

August, 1887.

PATHOLOGY AND TREATMENT OF SEPTIC DISEASES.

To the Editors of THE LANCET.

SIRS,—For some time past I have been anxious to lay my views before the profession upon the pathology and treatment of diphtheria and scarlatina.

In November, 1880, I sent a paper to THE LANCET upon reading in that journal a report of five fatal cases of diphtheria occurring in St. George's Hospital, with the peculiar treatment adopted at that time; I say peculiar, for it was strongly stimulating and tonic *ab initio*, under which the patients speedily succumbed. I then sought to show that the alterative and eliminating plan of treatment with which I commenced had been most successful, having only had two fatal cases under my care during three years of active practice. I ought to state that I always commenced by brushing off, as far as practicable, the false deposit on the tonsils and fauces with a strong solution of nitrate of silver, and continued this application daily while any deposit was observed on the surface. During the last few years, however, the science of bacteriology has done much to aid us in arriving at a more correct view of the pathology and treatment of diphtheria and scarlatina, as well as cholera. The scientific researches and experiments of Drs. Tyndall and Koch, M. Pasteur, and others, have lately demonstrated that we have chemical agents which will destroy the microbes and their spores in a very short space of time, which can be administered as remedies internally in these septic diseases: e.g., perchloride of mercury (1 in 20,000) will act as a microbicide in ten minutes; this, therefore, may be termed the prince of antiseptics. Chlorine and iodine, oil of mustard, and oil of peppermint are likewise very decided in their action as antiseptics, and may be utilised in the above-named diseases. As it is known that these micro-organisms multiply with frightful rapidity when once within the body, it is important to adopt energetic measures for their destruction and extermination without loss of time. To this end I would recommend in a case of diphtheria to commence by washing off the fungus-like deposit with a camel's-hair brush dipped in a solution of the perchloride of mercury or the liquor sodæ chloratæ. I should then administer a mustard emetic so as to dislodge and evacuate these micro-organisms from the stomach, œsophagus, and fauces. In half an hour, or as soon as the system had recovered from the effects of the emetic, I should give a dose of the liquor hyd. perchlorid. in a little strong peppermint water; this might be repeated in another hour, and, in about half an hour after this second dose of liquor hyd., a dessertspoonful or a medium dose of castor oil in peppermint water given as an effectual evacuant. Having cleansed the entire gastro-enteric canal of these pernicious atoms, those that have got into the blood must be disposed of in the way that Nature is wont to do—i.e., by the emunctories of the body,—aiding her in various ways: viz., by keeping the patient warm in bed in an airy apartment, administering diaphoretic salines with chlorate of potash, giving easily digested food—e.g., pure milk, beef-tea, barley water, and cocoatina. This treatment is all that is necessary for two or three days, especially while any febrile symptoms are present; tonics and stimulants in the early stage must not be given. Under the above regimen the system will very soon manifest salutary reaction by ridding it of the *materies morbi* under which it has been so distressed. Doubtless there are cases which will demand a course of ferruginous tonics for some little time, as it is well known these animalcules lessen the red particles of the blood.

In the administration of the liquor hyd. perchlorid., we should bear in mind that it is not only a special microbicide, but by its action on the liver it increases the biliary secretion, which is also admitted by many to be an antiseptic; and in order to strengthen our belief in this doctrine, we know that in cholera cases, as soon as the secretion of bile was restored we considered the patient tolerably safe; and, as Dr. Koch stated when writing on the cholera poison, "as soon as the dejections became feculent, the comma-like bacilli gradually disappeared and were not to be seen after recovery." It is tolerably well known, too, that during the visitation of cholera in our fair isle, the calomel treatment was the most successful. The College of Physicians advised the mist. cretæ co. c. opio to start with, and to be kept for use at all dispensaries, not knowing at that epoch the disease depended upon the energetic wriggling bacilli.

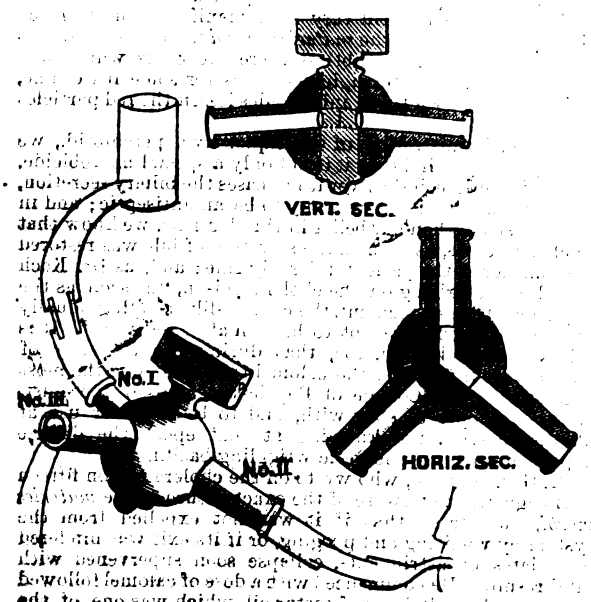
Dr. Geo. Johnson, who wrote on the cholera poison fifteen years ago, was not aware of the exact nature of the *materies morbi*, but stated that if it was not expelled from the system by vomiting and purging, or if its exit was hindered by opiates or astringents, collapse soon supervened with fatal results. He commenced with a dose of calomel followed by repeated small doses of castor oil, which was one of the most successful modes of treatment at that time—i.e., the eliminative. Now, I trust, were these bacilli to enter our system, we should screw them up and evacuate them with a mustard emetic followed by the above antiseptic treatment.

From an interesting article which I have just read in THE LANCET of July 23rd, it would go to show that I have been anticipating your views on the subject of bacterio-therapy, when you state that "in these days we find that the pathologist has outstripped the therapeutist." You further remark that we have to find out remedial agents sufficiently potent to destroy the bacterial host without injury to the body. You likewise allude to the all-important art of prophylaxis. One of the most frequent sources of diphtheria and scarlatina has been lately discovered in milk. A few

Digitized by Google

months since twelve fatal cases of diphtheria were registered in our neighbouring parish, Ealing, in as many days, which was traced to cow's milk. I wrote to the local paper warning the public against allowing animals to drink from stagnant pools, which at this season of the year especially are teeming with organic life, and is doubtless the *fons et origo mali*. While on this important point I should like the profession to agree with me in urging the advisability of all cow-keepers to give their animals, where practicable, the water of the company whence they draw their supply.

In the treatment of scarlatina with the above antiseptic plan, I would comfort the patient and stimulate the cutaneous surface by sponging the body all over with vinegar and warm water for the first three days, and the subsequent three days by skin inunction, as, I believe, is now usually practised as a prophylactic method, to be followed by two or three washings of the body with carbolic soap and warm water and much dry rubbing, which will complete the effective treatment of a severe and frequently intractable disease.



I am, Sirs, yours faithfully,

Fairholme, Hanwell, July 25th, 1887. EMANUEL MAY, M.D.

AN APPARATUS FOR WASHING-OUT THE STOMACH.

To the Editors of THE LANCET.

SIRS,—I can lay claim to no originality in the conception of the apparatus which I wish to bring under the notice of the profession. When in Germany last year I saw it used in the wards by Professor Kohlschutter of Halle, and it struck me at once as being superior to anything I had seen used in England for the purpose, and deserving therefore of a wider publicity. The essential part of the apparatus is a centre piece, consisting of a three-way stopcock, fitted with three outlet tubes. Of these outlets, No. 1 is attached (by india-rubber tubing with a glass interruption) to a vessel of water, or any other liquid to be introduced into the stomach;

No. 2, with its tubing and glass interruption, is continuous with the œsophageal tube; while No. 3, with similar fittings, leads into a receptacle placed on the floor for the waste fluid. To employ the apparatus (the vessel containing the fluid to be used is raised above the level of the patient) the stopcock is turned in such a manner as to connect Nos. 1 and 2, and fluid then passes into the stomach; when sufficient has been thus injected, the cock is turned so as to connect Nos. 2 and 3, and the centre piece lowered slightly; the contents of the stomach are thus by syphon action drawn into the waste receptacle; the performance can now be repeated as often as is deemed necessary, the only requisites being a continuous supply of fresh fluid in the upper vessel, and a slight raising and lowering of the centre piece, with corresponding alternations in the position of the tap. No. 1 and No. 3 can be connected after use to cleanse the tubing if required. Simplicity in management is one great recommendation of the apparatus, but its chief claim is its cleanliness, for nothing that has once passed into the stomach ever returns into the original vessel. The cost of the instrument is not excessive. Messrs. Krohne and Sesemann have made mine for me, the centre piece at a cost of 10*s.* 6*d.*; all the rest of the material need not cost more than a few shillings, as the quality of the tubing is of small moment, and œsophageal tubes are in the possession of most members of the profession.—I am, Sirs, yours obediently,

FRED. J. SMITH, M.R.C.P., M.B.,
Medical Registrar to the London Hospital.

West-street, Finsbury-circus, August, 1887.

THE SEWAGE OF LONDON.

To the Editors of THE LANCET.

SIRS,—"Sanitarian's" letter in THE LANCET of Aug. 6th, while admitting the polluted and foul state of the Thames from London sewage, advocates, as a remedy, the purification of the sewage by precipitation at Barking and Crossness, as well as at various stations within the metropolis, with manganate of soda and sulphuric acid, which never results, he says, "in the production of smelling products." "Neither," he says, "do such ingredients destroy those minute vegetable and animal organisms which are essential for the rapid purification of waters from admixed sewage residues." But suppose we were to admit that the sewage, as it escapes from the outfalls, is precipitated by such a process, the evil he refers to would not be removed. "Sanitarian" speaks of the improved condition of the Thames in 1885-6, when this process was in operation, but unfortunately in the autumn of the latter year I attempted a journey down the river to Barking with the view of ascertaining the state of the Thames at the outfall there, but the condition of the river was so fearfully foul that I found it almost impossible to get there, and when the steamer pulled up at Greenwich, being unable any longer to bear the smell, I was compelled to get off. One thing, I think, is absolutely certain: neither manganate of soda, nor sulphuric acid, nor chloride of lime, nor any other chemical agent will ever succeed in purifying the sewage of any large city, if used only at the stations and at the outfalls; it may be possible, no doubt, during dry weather, when the sewage leaves the outfalls, quietly to precipitate it; but there is this difficulty—and here the difficulty lies, and will ever lie: the *solid* portion of the excreta is not at the outfall to be precipitated. Moreover, in the dry weather it is then snugly lying in the drains under the dwellings of the residents of London, from which it can only be removed by the rainfall, and the rainfall is ever capricious in its operation; sometimes it is delayed for a week, a fortnight, or even a month, but when it does occur the solid excreta is quickly removed from its hiding place in the house drains into the sewers, in which at the upper part there are a great number of large storm outlets, and through these storm outlets the excreta, paper, &c., escape, and gain by that means admission into the rivers. In Birmingham there are about fifty of these storm outlets in the main sewers, and the Drainage Board has found out to its cost how impossible it is to cook the hare before it is caught, and it is this same difficulty the Metropolitan Board has to contend with. The solid portion of the closet soil being viscid and tenacious, it is, as I said before, always more or less retained in the house drains. I pointed that out to Lord Wemyss, who did me the honour of quoting my views in the House of Lords when the Smoke Abatement Bill was under discussion, and when their Lordships, acting in the interests of the residents of the metropolis, wisely threw out the Bill. Your correspondent admits that the state of the Thames at the present time, in consequence of the London sewage, is so bad that it is causing considerable apprehension to those who are responsible for it, and that it is as bad as, if not worse than, it was in 1884. I have shown that the process of purification at the outfalls, as recommended by "Sanitarian," will prove utterly useless and futile; whether we view the question of the utilisation of London sewage as a sanitary, an agricultural, or a financial question, it has hitherto failed in every instance under all these heads, and it will ever continue to fail. Unquestionably, the old midden system was very objectionable, but

Digitized by Google

the evils of that system were as nothing when compared with the frightful evils, both urban and suburban, which are produced by the present system of underground cesspools. Formerly the cesspool was at the further end of the yard or the garden; now it is under, and sometimes even in, the house itself. As it is necessary to convey the closet soil by some means to the outfalls at Barking and Crossness, it is obvious it must pass from the higher parts of London under the streets and houses before it can get there. If I recollect rightly, Sir Robert Rawlinson, who, by-the-bye, is responsible to a great degree for the present system, said at one of the Social Science meetings that "the district of Belgravia was as flat as a pancake, and but for the ventilators, he predicted, he said, a fearful epidemic in that locality." But, if I am not mistaken, the three factors of decomposition are air, heat, and moisture, and without these factors decomposition cannot take place, and if we have to deal with a foul smell underground, I should say these factors should be excluded from it. In London there are many instances where offensive smells emanate from these underground cesspools. In the House of Commons, where a large sum of money has been recently expended in perfecting the cesspool system, the foul odours are already returning. Johnson properly describes a drain or a sewer as a passage for liquid, and if drains and sewers are kept for that purpose, surely they would flush themselves; and it is equally obvious, if the sewage problem is to be solved, that the excreta sewage must be kept separate and distinct from the rainfall sewage, and that the solid portion of the closet soil must be intercepted at the fountain head, where it may be retained in hermetically sealed iron receptacles without the smallest danger, and in them it may be sent to the farmer for use on his arable land. If this were done, sewage utilisation would no longer be a failure, but it would become a sanitary, an agricultural, and a financial success. I have been over the sewage works of London, Croydon, Birmingham, &c., and if the watercloset system is to be continued, and if the sewage problem is to be really solved, I am convinced the solution of the question must begin where the solution of every difficulty usually begins: I mean at the beginning!—I am, Sirs, yours obediently,

Birmingham, Aug. 6th, 1887. EDWIN CHESSHIRE, F.R.C.S.

PAIN AND ITS INTERPRETATION.

To the Editors of THE LANCET.

SIRS,—So much debatable matter appears every week in your columns, that it is surprising that letters of criticism thereon are so few and far between. It would be uncharitable to suggest that this may be due to lack of interest in perusal or to want of energy in putting pen to paper in reply. Last week, however, there appeared an article upon the "Interpretation of Disease," which contains a series of statements so strangely at variance with universal experience, no less than with common sense, that I feel it is incumbent upon anyone who has read them to controvert them. Mr. H. Cameron Gillies, M.B., the author of the article in question, ventures the following among other assertions concerning pain and its causation: "*Pain never comes where it can serve no good purpose. Pain comes at the right time. The measure of pain which attends an injury or a disease is a prophecy, in that same measure of recovery.* It is in our knowledge that almost all inevitably fatal diseases are not attended with pain."

Now these statements, as is obvious from the context, refer to the beneficent utility of pain to the individual himself, and not in the wider sense in which it would be more possible to read them with patience and a guarded assent. Surely such fallacies scarcely required to be accentuated by italics to stamp them as such. What diseases are above all others "inevitably fatal"? Why, of course, that great class of malignant maladies which pathology comprises under carcinomata and sarcomata. Is pain absent there? Is pain purposive there?—purposive, that is, towards the utility of the individual. Yet Mr. Gillies does not except this great class, this *opprobrium medicinæ*, from his beneficent "law of pain." Pain, he says, in such cases would "serve no good purpose; there is no pain." Is this the grim comfort he would bring to a suffering woman tortured slowly to death by a sloughing scirrhus of the breast, or to a man, made almost unhuman and killed by inches by the slow yet sure ravages of a rodent ulcer? It is too late in the day to attempt to prop up a theory of the invariable and direct beneficence of pain, shutting the eyes to facts to save a teleological theory which experience and reason have alike discredited.

To a reverent believer in evolution pain is more nearly comprehended in its true light and meaning, and much of its sting removed in proportion to that comprehension. The gradual growth of the nervous system from the early dawn of consciousness—the mere sense of externality—up to the delicate and impressionable susceptibility from which we derive all that is best and noblest, has proceeded under the direction of a natural process of selection, and eventuated in the fittest's survival. It has thus come about that the advantage in the race which the sharp reprimand of pain on danger's approach bestowed has, with the intensified susceptibilities which we prize, also afforded us increased possibilities and opportunities of suffering. To the evolutionist much, if not all, is explained; "the mystery of pain," which Hinton helped to dispel, is lightened. Hinton demonstrated its relative nature, and the absence of any constant external antecedent of it. Here there is to be found the comfort which science affords—comfort in the knowledge that pain is in obedience to law, is bound up with the progress of the race. With this knowledge and with this hope, far more than with blind assertions as to the invariable beneficence of pain, one can "kiss the rod," and be

"Patient of pain, though as quick as a sensitive plant to the touch."

I am, Sirs, yours faithfully,

W. J. COLLINS, M.S., M.D., B.Sc. Lond.

Albert-terrace, Gloucester Gate, N.W., Aug. 15th.

To the Editors of THE LANCET.

SIRS,—My friend, neighbour, and adviser, Dr. J. J. B. Taylor of Ulverston, has obliged me with sight of a paragraph in THE LANCET on pain, the result of an inquiry from him, which again was prompted by a conversation between him and myself. May I venture to regard this as an introduction of myself as well as the subject? If so, I would like to submit the following queries:—1. Pain, in spite of its usefulness in the animal economy, nearly always has the air of an intrusion and a disturbance of that economy, but not absolutely so. The two fixed and normal pains in humanity are, it seems to me, those of parturition, limited to one sex, and those of dentition, limited to two or possibly more stages of development. It seems to me that these have a curious analogy, the dentition involving something of a tension of sensitive parts and extrusion of developed germs, although not, as in parturition, a separation from their matrix. It is an important question, Are there any other pains which can be viewed as fixed and normal, so as to take rank with these? It seems to me also that the higher vertebrates, at any rate in their domestic state, in which we know them best, sympathise with humanity *qua* parturition. Is there any knowledge available as to their wild state? And as regards their dentition—e.g., the changes noticeable in a horse's age-teeth—are any pains observed? 2. It seems to me that pain is not only preservative, but didactic—e.g., savage man finds travelling over rough ground painful, and devises mocassins, &c.; civilised man is prompted to discover anæsthetics and anodynes. Thus civilisation grows through pain, whereas pleasure, tending to absorb and satisfy, would never advance our progress, save as regards the means of procuring enjoyment, which, however, terminate in that enjoyment procured and do little to advance humanity. There is (to return to 1) a notable moral effect in the fixed and normal pain of parturition. It seems to impress the mother or dam in the interests of the offspring, and is allied in humanity to the tenacity of maternal affection, and reciprocally to the respect for maternal feelings, of which even hardened specimens of humanity commonly show a trace. And there seems to me to be, when all preservative and didactic uses have been satisfied, a surplus of pain in humanity, of which, I suppose, cancer may be taken as a typical case. It is my belief that this surplus can only be accounted for on moral grounds, as having a disciplerial tendency, not to the sufferers only, but to humanity at large. It is with this moral aspect of the whole question that I am chiefly concerned. But I should for obvious reasons be glad to have answers, so far as the state of our knowledge allows, to the above questions, and the benefit of any remarks to

Digitized by Google

which my own may give rise. I intended this when I began to be a private letter merely; but if you see fit to publish it, I have no objection, and I do not think my friend, Dr. Taylor, would have any.—I am, Sirs, your obedient servant,

HENRY HAYMAN, D.D.,
Rector of Aldingham; Hon. Canon of Carlisle.

Aldingham, Ulverston, Aug. 15th, 1887.

USEFUL EMPLOYMENT IN THE TREATMENT OF THE INSANE.

To the Editors of THE LANCET.

SIRS,—I have read with much interest the article in your issue of Aug. 6th on the Lunacy Commissioners' report, and am grateful for the prominence you give to occupation as a cardinal point in the treatment of the insane. The Commissioners have, I think, done well to call attention specially to this point, and to express a hope that more attention may be paid to it as a potent remedial agency in the treatment of the insane.

It is pointed out in the report that "the employment of patients of the private class in hospitals and licensed houses is attended with greater difficulty than that of patients in county and borough asylums," and the case of St. Andrew's Hospital, Northampton, is quoted as a notable achievement, inasmuch as *one-third* of the gentlemen in that establishment are engaged in gardening and farm work. This is very creditable to the energetic medical superintendent of that asylum, as it is only during the past two or three years that he has had premises extensive enough to allow the development of the employment system.

I believe I may claim what little credit there may be in being the first to ventilate in the columns of the *Journal of Mental Science* the advantages of employment in the treatment of mental diseases in the upper classes, having written a paper on that subject for the *Journal* of July, 1882. For the encouragement of those medical proprietors and superintendents who may be afraid of the "much thought, trouble, and ingenuity" mentioned in the Commissioners' report, I should like to state that I have found no reason to depart from the practice I adopted seven years ago of insisting on regular occupation for every able-bodied patient in my asylum, and that I have now not the slightest trouble in getting at least *two-thirds* of my gentlemen patients (i.e., all those who are physically fit for work) to engage in regular useful occupation, which percentage compares favourably with the average in county and borough asylums of $\frac{6}{10}$, or the "notable achievement" of St. Andrew's Hospital quoted above, where *one-third* of the male patients are employed. I am perhaps rather too enthusiastic on this subject, but I firmly believe that it has only been found possible to abolish restraint and seclusion in English asylums, and the use of locked doors and airing courts in some Scotch asylums, by reason of the increased and intelligent interest betrayed on the part of asylum superintendents in the useful and rational employment of their patients.

I am, Sirs, your obedient servant,

DAVID BOWER, M.D.

Springfield House Asylum, Bedford, Aug. 11th, 1887.

BORACIC ACID AS A FOOD PRESERVATIVE.

To the Editors of THE LANCET.

SIRS,—The question regarding the use of borax and boracic acid as food preservatives, upon which a joint preliminary report, referred to in your issue of the 13th inst., was recently presented to the Kensington vestry by Dr. Dudfield and myself, arose through my having found boracic acid in a sample of *potted cream* submitted to me officially for analysis, and subsequently in several samples of milk.

It is obvious that if the vendors of foods containing boracic acid are to be proceeded against under the Sale of Food and Drugs Act, the proceedings must be taken under the most severe sections of the Act—those, namely, which are intended to provide against the admixture of any substance actually known to be injurious to health, or likely to be injurious to health, with articles of food; and it therefore becomes necessary to obtain definite evidence as to whether boracic acid and borax can or cannot be considered as injurious additions. Very little information upon this head is forthcoming; but, as you very justly remark in your annotation, what little there is is very decidedly against the use of the drug. This, indeed, is the conclusion that one would naturally anticipate on *a priori* grounds, and I may perhaps say that in the early part of 1886, chiefly upon such grounds, I made some remarks in public against the use of boracic acid preservatives, which were subsequently reproduced in the *Chemical News*.[1] In the report above referred to we did not think it necessary to give the full text of Dr. Förster's experiments and conclusions; but I am very glad that this has now been put before the readers of THE LANCET in Mr. Charles Hancock's excellent translation from *Dingler's Journal*, for the matter is unquestionably one of great public interest and importance. The drug was present in smaller amount in the samples of milk than in the sample of potted cream above referred to. The latter, in fact, contained so much of it that its taste was very distinctly perceptible.

Finally, I venture to draw your especial attention to two passages in our joint report. They are as follows:—

"An eminent authority whom we have consulted refers to the tendency of these substances to set up diarrhœa, a disease very prevalent in hot weather, when the preservative is most used to prevent that change which milk and cream are apt to undergo, rapidly, at a high atmospheric temperature."

"We desire to say, in conclusion, that, though in the present state of our knowledge the injurious action of very small doses of borax or boracic acid, even in the case of infants, and even having regard to the doses being continuous, may perhaps be considered as 'not proven,' it will probably become a question whether the use of any known preservative, in lieu of refrigeration, in any amount, however small, should not be prohibited, in view of possible and indeed probable abuse, and while doubt exists as to the action of the drug employed."

These remarks will, I believe, on consideration, be found tolerably suggestive.

I am, Sirs, yours faithfully,

CHARLES E. CASSAL,
Public Analyst for Kensington, St. George's, Hanover-square, and High Wycombe.

Town Hall, Kensington, Aug. 16th, 1887.

"DISEASE AND MEDICAL ATTENDANCE AT WORKHOUSES."

To the Editors of THE LANCET.

SIRS,—As there have lately been several letters in THE LANCET with regard to the question of admitting "a second medical opinion into the workhouse," my experience in this matter may perhaps interest your correspondents.

I am the resident medical officer of the Chorlton Union Hospital and Workhouse, Manchester, and in the male lunatic wards of the hospital there was some three or four years ago a patient suffering from dementia, and incurably insane. This patient's friends wished him to be removed from the workhouse to a private asylum, and they sent their own medical attendant to visit him in the workhouse. This gentleman, a qualified surgeon, saw the patient in the workhouse, examined him, and filled up the papers necessary for his removal to an asylum. He never communicated with me, and I knew absolutely nothing about the matter until after the patient was removed from the workhouse. I reported the matter at the time to the guardians, and the clerk to the guardians ruled that "a pauper, or the friends of any pauper, had a perfect right to send for any medical man, and such medical man had a perfect right to treat such pauper in any way he pleased, without communicating with the medical officer of the workhouse at all." These were the exact words used by the clerk, which of course settled the matter. I am, Sirs, yours obediently,

August, 1887. J. S. ORCHARD, M.D.

[1] March 12th, 1886.

MANCHESTER WATER SUPPLY.—In view of the rapidly-diminishing quantity of water in store at the Manchester Corporation reservoirs, the authorities have had their attention directed to the question of procuring a further supply from some flooded collieries at Moston, a village adjacent to the city. Samples of the water, which is stated to be of splendid quality and practically inexhaustible, have been taken for analysis.

LIVERPOOL.

(From our own Correspondent.)

THE SUMMER ASSIZES.

MR. JUSTICE DAY concluded the business of the assizes on the 10th inst., having sat for eleven days in the Crown Court. Among other cases were two charges of murder, both by the knife. In one the left lung was wounded, and death occurred shortly after the admission of the deceased man into the Royal Infirmary. The prisoner was found guilty of manslaughter. In the other case the deceased was wounded in the abdomen, and lingered for some time after his admission into the Royal Southern Hospital. His assailant was found guilty of murder, but recommended to mercy.

RIVER POLLUTION.

It is greatly to be hoped that our sanitary authorities will take time by the forelock and steps to purify the river Mersey before it becomes as foul as the Liffey, the Clyde, or the Thames. For years past there have been most unsavoury odours perceptible at low water, especially in hot weather, and were it not for its breadth and the strength of its tides matters would be much worse. Any scheme for diverting the sewage from the river must, of course, be very costly. But it will become more so by keeping; and, taking into account the immense population on both sides of the river, the continuance of this sewage-pollution must be fraught with the greatest danger to them, as well as to all on board vessels stationed in the river.

CONVERSION OF ANOTHER CITY CHURCHYARD INTO A RECREATION-GROUND.

Until within the last few months the churchyard attached to St. Peter's Cathedral Church presented a most ghastly spectacle. It was a wilderness of gravestones, with rank grass here and there, and was a receptacle for all kinds of rubbish. By a mutual arrangement, made between the ecclesiastical and corporation authorities, all this has been changed, and the site has been converted into a recreation-ground of most pleasing appearance. To those who, from absence, have not seen the gradual transition, the change is startling, the wilderness of graves having been converted into walks, grass plots, trees, and shrubs. What is still more pleasing is that it is largely availed of as a place for rest and recreation, seats being provided in different parts, many being induced to leave the adjacent crowded thoroughfare and rest awhile.

THE HOLIDAY SEASON.

There was a small proportion of local representatives at the Dublin meeting, and there will be some at the International Medical Congress at Washington. At present the holiday season is in full vigour, both with medical men and laymen. For those who can go on a distant holiday, Liverpool offers great facilities, it being perfectly easy to go direct to all the more favourite English, Scotch, Welsh, and Irish seaside places, while, for those who prefer a longer distance, trips to America, the Mediterranean, Spain, or Portugal are easily obtained. But there are some persons, professional and lay, to whom holidays are as angels' visits, few and far between. To them Liverpool offers a very fair substitute in the very accessible and popular seaside resorts of New Brighton and Hoylake, where comfortable lodgings can be obtained, and this city can be reached in a very conveniently short time. Southport, though more distant, is soon reached, and on the same line of rail are several very attractive townships and villages, where a complete change of air may be obtained for jaded citizens without taking them out of reach of their duties.

Liverpool, Aug. 16th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

INVITATION TO THE BRITISH ASSOCIATION.

A PUBLIC meeting was held in Newcastle last Wednesday, Sir B. C. Browne (the Mayor) presiding, when it was resolved to invite the British Association to this city in 1889. A very hearty spirit prevailed at the meeting, and Lord Armstrong promised a contribution of £200 towards the expenses, should it be required. On the part of the medical profession, Drs. Embleton and Philipson expressed the feeling that they would not be behind others in endeavouring to make the meeting a success. Dr. Philipson further said, as to the University of Durham and the College of Medicine, he had no doubt they would render all the aid they could. The last time the British Association met in Newcastle was in 1863.

NEWCASTLE ROYAL INFIRMARY.

It will be remembered that in a late note I mentioned that some of the Chinese sailors who were ill aboard the *Foo Nan* in the Tyne were admitted and treated in the Infirmary. The Chinese admiral has now written a grateful letter of thanks for the attention his men received, at the same time enclosing a cheque for £40 as a donation to the institution. At a late meeting held at the infirmary a report was made to the governors of the improved financial state of the house; an alteration was also made in one of the rules requiring, in the case of the admission of a workman to the benefits of the infirmary, if he be employed by an individual or a firm not subscribing to the institution, that a letter shall be written to the employer or firm requesting the adoption of a system of regular workman's contributions or the repayment of the expenses incurred by receiving the patient into the infirmary.

DEATH OF SEPTIMUS W. RAYNE, F.R.C.S.

The death of Mr. S. W. Rayne of this city, I regret to see, is announced as having taken place at Winchester on the 10th inst. Mr. Rayne, who was in his seventy-first year, had retired from the active duties of the profession a couple of years ago, and resided in the south of England. Mr. Rayne was a pupil of the late Mr. Liston. He became M.R.C.S. in 1839, L.S.A. in 1842, and F.R.C.S. Eng. in 1873. He was a very active practitioner, and as surgeon to the police (a post he held for nearly forty years) and North-Eastern Railway Company, his offices brought him a large amount of medico-legal practice, more than usually falls to a general practitioner. He also for many years had a very large private practice. He discharged all his duties with marked fidelity, and his death narrows the circle of the older practitioners of Newcastle, while he will be much regretted for his kindness of heart and many good qualities. I mentioned in a letter about two years ago that on Mr. Rayne's resignation of the police surgeoncy our Town Council accorded him a unanimous vote of thanks for his valuable services, the terms of which were, by direction of the Council, engrossed on vellum.

DUBLIN.

(From our own Correspondent.)

THE DUBLIN HOSPITALS BILL.

IN view of the widespread dislike to the provisions of the proposed Dublin Hospitals Bill, the following resolutions of the Council of the Dublin Hospital Sunday Fund adopted at a recent meeting, may be of interest: "1. The Council of the Dublin Hospital Sunday Fund have had under consideration the Dublin Hospital Bill introduced by the city members. The Council do not at present offer an opinion on the general merits or demerits of the Bill, but wish to observe that the bill provides for the payment to the proposed Hospital Board of the Hospital Sunday Fund and its disposal by that board. The Council are satisfied that the subscribers to the fund would not consent to entrust the management of the fund to the proposed Board, and they desire to impress upon the promoters that they must not reckon upon the Hospital Sunday Fund forming any part of the proposed revenue of the Board." "2. The Dublin Hospital Sunday Fund Council, believing that, in the interests of the Dublin hospitals, it is desirable that a committee should be formed to take into consideration the various clauses in the Bill and their bearing on the hospitals of Dublin, recommend that a committee be appointed with this object, consisting of the Distribution Committee and the honorary secretaries of the Dublin Hospital Sunday Fund, and some members of each of the hospitals benefiting by the fund, having under fifty beds, and two members from each hospital of over fifty beds."

HEALTH OF IRELAND: QUARTERLY RETURN.

The birth-rate for the June quarter was 0·7 under the average rate for the corresponding quarter of the last five years; while the deaths were slightly above those registered in the second quarter of 1886. Compared with those for the corresponding quarter of last year, the returns of pauperism, furnished by the Local Government Board, show a decrease of 705 in the average number of workhouse inmates on Saturdays during the quarter, and a decrease of 42,833 in the average number of persons on out-door relief. The registrars in their notes report the presence of the following diseases: Measles in 37 districts, rötheln in 6, scarlatina in 36, whooping-cough in 39, and fever in 32.

DISTRICT LUNATIC ASYLUMS, IRELAND.

A Bill has been issued this week to amend the provisions for superannuating the officers of Irish district lunatic asylums. The Bill provides that such officers shall be eligible for superannuation annuities if incapacitated by sickness or age, or if they have served in the asylum for not less than fifteen years, they being fifty years of age or upwards. The retiring allowance is to be paid out of the rates and funds applicable to the maintenance of the asylum, and the amount paid is not to exceed two-thirds of the annual salary, rations, and other allowances. It is required that His Excellency the Lord-Lieutenant approve all such grants.

At Dungannon, last week, Quartermaster Sergeant Armitage committed suicide by taking a quantity of cyanide of potassium. Death, as is usual in poisoning from this substance, was very rapid.

Dublin, August 16th.

Obituary.

GUSTAVUS CHARLES PHILIP MURRAY, M.D.

THE tidings of the sudden death of Dr. Murray, at the comparatively early age of fifty-six, must have come as a great shock to a large and wide-reaching circle of patients and friends. He had been suffering for some time from a degree of general malaise and failure of strength that made the daily calls and cares of practice a burden rather than the pleasure they had been to him; but his sudden death from heart failure, on the 7th of this month, at his residence in Great Cumberland-street, was a quite unexpected and very severe blow.

Dr. Murray, who was born in 1831 at Port of Spain, Trinidad, was the youngest son of the Hon. Edward Murray, marshal of that island. Through boyhood and youth his health was so delicate that his general education was chiefly obtained at private schools, in England, and he was obliged twice to revisit his birthplace for his health's sake. When his choice of a profession had been made, he became a student in the medical school of King's College, in the days of Todd and Bowman, of Fergusson and Partridge, and when Arthur Farre was Professor of Obstetrics. There young Murray worked well and got a good hold of the science and art of medicine; with his ardent spirit he could hardly have done otherwise; and there, as elsewhere throughout his career, he made friends who remained friends for life. In 1856 he became a member of the Royal College of Surgeons of England, and after that he studied at Edinburgh and at Vienna, taking the M.D. degree of the University of Edinburgh in 1860. Having, somewhat early we imagine, decided on seeking obstetric practice as his specialty, Dr. Murray settled down without loss of time in Green-street, which, if not the rose, is, as every medical man knows, very near the rose of medical position, and began to look out eagerly for appointments and patients. The former he obtained quickly, and through them he rapidly gained very largely the practical experience that every true medical man so hungers after. He was for several years physician-accoucheur and physician for the diseases of women and children to the St. George's and St. James's Dispensary; physician, and later on consulting physician-accoucheur, to the St. Pancras Provident Dispensary; and for very many years, and down to the day of his death, he was obstetric physician to the Great Northern Central Hospital. We cannot pretend to enumerate here all the honorary appointments that Dr. Murray at various times held, and to the work in which he gave so much valuable time and thought, but we must note his connexion with the Establishment for Gentlewomen in Harley-street, where he did excellent work, and to which he was still physician for the diseases of women when he died. He was a Fellow of the Edinburgh Obstetrical Society; and was one of the original Fellows of the Obstetrical Society of London, in which he filled in succession almost all the offices of honour and work, except the highest of all—that of president; for when that crowning distinction was offered to him, in 1884, the wear and tear of practice had so far told on him that, with great reluctance, and in deference to medical advice, he felt obliged to decline the coveted honour.

Very early in his career Dr. Murray began to send contributions to the Obstetrical Transactions and Journal, and to the medical papers; but his special fitness for the line of work he had chosen was soon recognised, and the demands of practice gradually more and more absorbed his time and thought, so that he ceased to write, and had to be content, as many other hard-worked medical men have been, to make known the results of his experience and observation orally, instead of putting them on record for the benefit of future as well as of present practitioners.

Dr. Murray was markedly skilful and successful in the treatment of the diseases of women and children, but it will be generally admitted that he especially excelled in the practice of midwifery. His manual dexterity was very great, and served him well in the management of difficult labours. And his judgment was equally good. He knew when to wait, and at what moment to interfere; and the natural result was that as an accoucheur he was highly successful, and his counsel and help were greatly valued by the numerous practitioners who called him in consultation. In untiring devotion to the patients committed to his charge, and in the tenderest regard for their feelings, Dr. Murray could not be surpassed. No trouble was too great for him to take when patients were concerned. He would sacrifice for them his time, convenience, and health in the most unsparing manner. Nor was this devotion, in his case, but a phase of a merely professional instinct. In him it was the outcome of kindness of heart and a sympathetic nature which endeared him to his friends and fellow-workers as much as to the sick and suffering, who relied with a happy confidence upon the physician who never failed them.

In social life Dr. Murray's cheeriness of manner, which was rarely wanting, made his companionship pleasant and very welcome, and his somewhat keen appreciation of the humorous side of life had its share in making him a very popular member of our profession. He will be long and sorely missed, for he possessed qualities which, happily for human nature, even the ever-increasing struggle for existence in professional life has not yet succeeded in rendering less acceptable and endearing.

In 1856 Dr. Murray married Fanny Tryphena, the daughter of John Yearsley, Esq., of The Moors, Cheltenham, who and a daughter and six sons are left to lament their loss. The second son, Mr. Stormont Murray, has followed in his father's steps, and is in practice in London.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen have been duly admitted Licentiates of the College:—

Barrett, William, Ashton-under-Lyne.
Green, Frederic W. Edridge, St. Bartholomew's Hospital.
Lewis, Ernest Edward, Middlesex Hospital.
Phillips, Stanley Clyde, Plymouth.
Trevelyan, Basil Riddell Trevelyan, Clifton.
Waterhouse, Herbert Furnivall, Dunoon, Scotland.
Woodward, William, St. Bartholomew's Hospital.

THE Jubilee of the Queen was commemorated at Southend on the 13th inst. by the laying of a memorial stone of the first local hospital, to be called the Victoria Hospital.

ON the 13th inst. a conference of dentists was held in Dublin for the purpose of establishing an Irish branch of the British Dental Association.

VACCINATION GRANT. — Dr. W. J. Smyth, Shipley, Yorks, has obtained the grant for efficient vaccination in his district (fourth time).

THE subscriptions in aid of the proposed Victoria Infirmary at Glasgow now amount to nearly £14,000. The committee are unwilling to begin building operations until the funds amount to about £20,000.

ARRANGEMENTS have been made with a view to the transfer of the Bradford Fever Hospital to the Corporation of that town being completed and possession being taken on the 1st prox.

THE 39th annual meeting of the subscribers to the Weymouth Sanatorium was held on the 4th inst., when satisfactory medical, financial, and general reports were presented and adopted.

BEQUESTS.—The late Mr. Thomas Synnott has left £200 to Jervis Street Hospital; £100 to the Mater Misericordiæ; £100 to the Hospital for Incurables; and £300 to Michael's Hospital, Kingstown.

ON the 17th inst. a portion of the burial ground in the rear of St. James's Church, Hampstead, amounting to about two and a half acres, was formally opened and dedicated to the public as an open space.

UNIVERSITY OF EDINBURGH.—We are asked to state that to the name of Daniel Mowat, in the list of gentlemen who were announced in our last issue as having obtained the M.D. of the University, should have been prefixed the sign indicating that his thesis received commendation.

ON the 10th inst. the Mayor of Bradford (Alderman Angus Holden) formally opened a temporary building which is to serve the purpose of the Bradford Hospital for the Sick Children of the Poor until funds are raised for a permanent and larger hospital.

RABIES IN CHESHIRE.—At the Macclesfield County Police Court on the 16th inst. the magistrates issued an order directing dogs to be kept under control throughout the whole of the Macclesfield district until further orders. A similar order expired a month ago, and since then several cases of rabies have occurred in the district.

AFTER much negotiation between the Folkestone Hospital Committee and the Government, the latter have agreed to restore the old battery site to the Earl of Radnor, from whose estate it was severed some years ago. The Earl of Radnor will transfer the site to the town authorities for the erection of a new hospital.

MR. H. C. RAIKES, M.P., visited the Morley House Seaside Convalescent Home, St. Margaret's Bay, on the 11th inst., for the purpose of opening the new wing erected by Lord Wolverton, who had contributed £1000 to the institution, in order that provision might be made for four London postmen convalescent from accident or disease.

THE DARENTH ASYLUM.—On the 6th inst. the managers of the Metropolitan District Asylums paid their annual visitation to the establishment under their control at Darenth, in which 800 imbeciles and harmless insane inmates are accommodated. The result of the inspection was reported as satisfactory, and the officers were congratulated upon the state of efficiency in which they kept the institution.

ROYAL UNIVERSITY OF IRELAND.—The following Exhibitions and Honours have been awarded at the First Examination in Medicine:—Exhibitions: First Class (£30), George Hewitt Frost; Second Class (£15), Katherine M. Maguire. Honours: First Class, G. Hewitt Frost; Second Class, Katherine M. Maguire, James B. Moore, Patrick McGann, Robert Fraser Moore. Upper Pass Division: James F. Carroll, Robert J. Gordon, Isabel W. Harper, James J. Thompson, Michael Toomey.

RETIRING ALLOWANCE.—On the 13th inst., at the weekly meeting of the Board of Guardians of the Caistor Union, attention was drawn to the fact that the visiting justices had recommended to quarter sessions an allowance to Dr. Palmer, on retiring from the post of medical officer of the Baumbridge Lunatic Asylum, Lincoln, of £500. After some discussion, the board decided to reaffirm their original resolution on the subject in favour of a pension of £350 a year only.

MEDICAL NOTES IN PARLIAMENT.

Teaching University for London.

IN the House of Commons on the 12th inst., Mr. W. H. Smith informed Mr. Bryce that the petitions praying for the constitution of a teaching university for London had been referred by Her Majesty to a committee of the Lords in Council, to consider and report upon. The Government did not at present contemplate the appointment of a Royal Commission to inquire into the subject.

Volunteer Medical Officers.

ON the 16th inst., Sir G. Hunter asked the Secretary of State for War whether there was any objection to the adoption of the recommendations of the Volunteer Medical Association with reference to rank &c. of Volunteer medical officers submitted to the War Office. The recommendations were as follows:—(1) That all appointments to the Volunteer Medical service should in the first instance be to the rank of acting-surgeon. (2) That acting surgeons upon obtaining the proficiency certificate should be commissioned and gazetted as surgeons. (3) That the substantive rank of surgeon-major should be given after twelve years' service, as in the Army, after such examination as may be deemed necessary. (4) That the whole of the medical officers be placed in a seniority list under the heading "Volunteer Medical Staff," the regiment or company of the staff corps to which the officers may be attached being placed after his name.—Mr. E. Stanhope, in reply, said that he was able to approve generally the proposals of the Association, but that some questions of detail still remained to be considered. He might, however, say that the grant of the rank of surgeon-major to Volunteer Medical officers after twelve years' service, and the insertion of their names in the Army list as Volunteer Medical Staff, would be approved.

Infant Mortality.

In reply to Mr. Picton, Mr. Ritchie said that inquiries had been instituted in thirty large towns and cities of England and Wales, not only with regard to diarrhœa, but in relation to choleraic outbreaks. The inquiries extended over six weeks of the year during which the disease was most fatal. As they progressed it became necessary to initiate fresh lines of search. To show the magnitude of the matter he might say that there were no less than 15,936 cases of deaths from diarrhœa registered in the third quarter of last year. The work was now actively progressing, and the board hoped that when the result of the present summer was obtained, they would be able to prepare a summary report of the whole inquiry. He was aware that several local authorities had for six years been incurring expense for meteorological observations, and the investigations had been of great service.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BIGGS, CHARLES E. F. M., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Third District of the Malmesbury Union.

EMMERSON, J. B., M.D. Durh., M.R.C.S., has been appointed Certifying Surgeon under the Factory Act to the Biggleswade District, vice C. P. Stevens, resigned.

FISHER, H. HOLDRICK, M.B. Lond., L.R.C.P. Lond., M.R.C.S., has been appointed Senior Resident Medical Officer to the Hospital for Sick Children, Pendlebury, Manchester, vice Kurshaw, resigned.

MACLAGAN, CHARLES G., M.B., C.M. Ed., has been appointed Medical Officer for the Berwick District of the Berwick Union, vice Mackay, resigned.

MADDOX, RALPH H., M.B. Ed., M.R.C.S., has been appointed Resident House-Surgeon to the Edinburgh Maternity Hospital.

MARTIN, JOSEPH H., M.R.C.S., L.S.A., has been appointed Medical Officer for the Warboys District of the St. Ives Union.

PRICHARD, RICHARD, M.D., C.M. Glas., has been appointed Medical Officer of Health to the Cardiff Union Rural Sanitary Authority, vice F. W. Granger, M.R.C.S., deceased.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM GENERAL HOSPITAL.—House Governor. Salary £300 a year, with board and apartments.

BRADFORD INFIRMARY.—Junior House-Surgeon. Salary £50 per annum, with board, residence, and washing.

BRIGHTON AND HOVE LYING-IN INSTITUTION—House-Surgeon. Salary £120 per annum, with furnished apartments, gas, coals, and attendance.

CANCER HOSPITAL, Brompton, S.W.—Resident Assistant House-Surgeon. Honorarium £35 per annum, with board and residence.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Assistant Physician.

DENBIGHSHIRE INFIRMARY, Denbigh. — House-Surgeon. Salary to commence at £35 per annum, with board, residence, and washing in the house.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Surgeon to Out-patients.

GAINSBOROUGH FRIENDLY SOCIETIES MEDICAL ASSOCIATION.—Resident Medical Officer. Salary £166 per annum, together with midwifery fees, house rent, rates, &c.

Digitized by Google

JARROW-ON-TYNE MEMORIAL HOSPITAL.—House-Surgeon. Salary to commence at £130 per annum, with board and residence.

LIVERPOOL DISPENSARIES.—Two Assistant Surgeons. Salary £80 per annum each, with apartments, board, and attendance.

MANCHESTER ROYAL INFIRMARY.—Resident Surgical Officer. Salary £150 per annum, with board and residence.

NORFOLK AND NORWICH HOSPITAL.—Resident Secretary and House Steward. Salary £100 per annum, with board and furnished apartments.

PAROCHIAL BOARD OF PENNYGOWN AND TOROSAY.—Medical Officer. Salary £100 a year.

ROYAL BERKS HOSPITAL, Reading.—Assistant House-Surgeon. Board and lodging, but no salary.

ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.—Assistant House-Surgeon. Salary, with board and residence, £60 per annum.

ST. PETER'S HOSPITAL FOR STONE, Henrietta-street, Covent-garden.—House-Surgeon. Honorarium (for six months) 25 guineas, board, lodging, and washing.

ST. SAVIOUR'S UNION INFIRMARY, East Dulwich-grove, Champion-hill, S.E.—Assistant Medical Superintendent. Salary £130 per annum, with furnished apartments, board, and washing.

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY.—Resident Medical Officer. Salary £60 per annum.

Births, Marriages, and Deaths.

BIRTHS.

CASSIDY.—On the 14th inst., at Harley-street, Cavendish-square, the wife of Joseph Lamont Cassidy, M.D., of a son.

COX.—On the 12th inst., at Claverton-street, S.W., the wife of J. Leslie Cox, L.R.C.P. Ed., of a daughter.

EMMETT.—On the 10th inst., at Woodville, Kingston-road, Portsmouth, the wife of Richard Emmett, M.R.C.S., L.R.C.P.Lond., of a daughter.

HAIG-BROWN.—On the 8th inst., at Charterhouse, Godalming, the wife of Clarence W. Haig-Brown, M.D., of a daughter.

HOOLE.—On the 16th inst., at Parkhurst-road, N., the wife of Henry Hoole, M.D.Lond., of a son.

WILLEY.—On the 16th inst., at Elmhyrst, Bromley, Kent, the wife of Henry Willey, M.B.Lond., F.R.C.S., of a daughter.

WILSON.—On the 11th inst., at the Free Church Manse, Liberton, Midlothian, the wife of Claude Wilson, M.D., of a daughter.

MARRIAGES.

DAVIDSON—BROWN.—On the 9th inst., at St. James's Church, Nottingham, Charles Robert Davidson, M.B., M.R.C.S., to Emily, eldest daughter of John Brown, Esq., of Park Valley.

FAWCETT—LLOYD.—On the 6th inst., at the Parish Church, Conwil Caio, Carmarthenshire, W. J. Fawcett, Surgeon-Major, Army Medical Staff, to K. M. Alice, younger daughter of the late Charles Lloyd, Esq., of Brunant.

HARTLEY—DAVIES.—On the 6th inst., at the Parish Church, Oswestry, Horace Hartley, M.R.C.S., L.R.C.P., to Nora, daughter of the late Henry Davies, Solicitor, Oswestry, Salop.

KENYON—WILTON.—On the 3rd inst., at St. Michael and All Angels', North Kensington, W., George Hebert Kenyon, M.D., to Annie Caroline, younger daughter of the late Rev. Edward Wilton, M.A.Oxon., Vicar of Osberton, Notts, and Domestic Chaplain to the late Earl of Galloway.

LIMONT—JACKSON.—On the 11th inst., at Crosthwaite Church, Keswick, by the Rev. H. D. Rawnsley, M.A., assisted by the Rev. J. S. Ostle, M.A., James Limont, M.B., M.R.C.P., of 3, Eldon-square, Newcastle-on-Tyne, to Margaret Jessie, daughter of the late Richard Jackson, Esq., of Liverpool.

PARTRIDGE—LOADER.—On the 10th inst., at St. Mark's, Coburg-road, Old Kent-road, S.E., William Thomas Partridge, L.R.C.P., M.R.C.S., to Letitia Rose, only daughter of Alfred Loader, Esq., of 60, Trafalgar-road, S.E.

POTTER—KNOCKER.—On the 15th inst., at All Hallow's, Tottenham, by the Rev. Prebendary Wilson, M.A., Vicar. Edward Furniss Potter, M.R.C.S., L.R.C.P.Lond., of Hull, to Ada Florence, second daughter of Charles Knocker, of Tottenham.

ROSS—ANDERSON.—On the 9th inst., at St. Paul's Church, Edinburgh, John Ross Home Ross, M.B., C.M., to Julia Caroline, eldest daughter of C. F. White, Esq., of Whitby, and widow of Charles F. Anderson, Esq.

STATHAM—GILL.—On the 3rd inst., at Kirk Malew, Isle of Man, Reginald Whiteside Statham, M.R.C.S., L.S.A., to Nessy, third daughter of the Rev. Hugh Stowell Gill, M.A., Vicar of Malew, and Rural Dean.

DEATHS.

GIBSON.—On the 8th inst., at Orton, Westmoreland, Thomas Gibson, M.D., M.R.C.S., J.P., aged 53.

GILLESPIE.—On the 12th inst., at Ticehurst, John Williams Gillespie, M.D., late of 25, Porchester-terrace, and formerly of the 5th Fusiliers and of the Isle of Mauritius.

POTTER—On the 12th inst., at North-street, Romford, Essex, Charles Potter, L.S.A., aged 73.

RAYNE.—On the 10th inst., at Winchester, S.W. Rayne, F.R.C.S.Eng., of 6, Hyde-park Mansions, and late of Newcastle-on-Tyne, in his 71st year.

WILLIAMS.—On the 7th inst., at Meadhurst, Eastbourne, W. D. Williams, M.D.Cantab., of Belmont Lodge, Reigate, in the 80th year of his age.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE STUDENTS' NUMBER OF "THE LANCET" will be published on Saturday, September 3rd. Those gentlemen holding official situations connected with medical institutions in the United Kingdom who have not yet forwarded the necessary information to our Office for publication in that number are earnestly requested to send it *without the delay of a single post.*

THE SANITARY CONDITION OF THE PALACE OF WESTMINSTER.

NOTWITHSTANDING the expense which has been incurred in perfecting the drainage beneath the Houses of Parliament, complaint is still made that the atmosphere of the Palace of Westminster is vitiated by disagreeable effluvia. An explanation of this serious annoyance has been offered by Mr. Bailey-Denton, who maintains that the noxious odours are due to the escape of what is called "ground air" from the subsoil of the Palace. The Thames at Westminster is polluted by the main drainage, and the tidal water of the river, as it passes and repasses along the face of the Embankment wall in front of the Houses of Parliament, finds its way in and out under the wall, thereby saturating the subsoil. Having thus percolated into and beneath the foundations of the Palace, the water rises and falls with the action of the tide, and the foul air is forced upwards into the Houses of Parliament.

Wounded.—We must refer our correspondent to the Secretary of the St. John Ambulance Society, St. John's Gate, Clerkenwell.

THE UNQUALIFIED ASSISTANT.

To the Editors of THE LANCET.

SIRS,—The vexed question of the right of the unqualified man to practise is continually cropping up in the medical journals. One has only to refer to the advertisement sheet of THE LANCET to see how overcrowded the profession is. Yet, whilst doing all in our power to stop further ingress among our ranks, would it not be fairer, more in the spirit of "as we ourselves would be done by," to let him, within safe and easily-defined limits, run his life unmolested? Many of this unfortunate class have been following their calling for years, and are too old to gain a livelihood by other means. Take this from them, and the breadwinner of many a family is taken also. None of us, even in these hard times, wish this. At the most it is not a very great slice out of our loaf, and each year it will be smaller, until the unqualified man will be as rare as the once familiar "in practice prior to 1815."

I am, Sirs, faithfully yours,

Aug. 15th, 1887. D. F. J.

BERLIN MARRIAGE STATISTICS.

Some interesting figures with regard to marriages in Berlin have been issued by the Statistical Office in that city. It appears that, of the 13,866 marriages which took place in 1885, only 100 were between blood relations—viz., 95 between cousins and 5 between uncles and nieces. Among men there were 11,911 first marriages, 11,122 being with spinsters, and 799 with widows or divorced wives. There were 1905 second and later marriages among men, 1441 being with spinsters and 504 with widows and divorced wives. Of the widowers who re-entered the married state, 611 did so within a year of bereavement, 359 within two years, 138 within three years, and 92 married again between three and four years after bereavement, the number of re-marriages falling considerably after this. One widower married after living single over thirty years, and eight divorced couples were re-married, the husband being in one case seventy years old.

Indignant has not enclosed his card.

BODY RESISTANCE TO ELECTRICAL CURRENT.

To the Editors of THE LANCET.

SIRS,—In a letter which appeared in THE LANCET of July 30th, p. 239, Dr. Stevenson touched on the resistance of the body with a needle attached to one pole beneath the skin. This resistance he estimates at 300 ohms; and doubtless in some parts of the body—for example, in the palms of the hands, this is by no means too high. Reference is also made to Dr. Apostoli's electrical treatment of uterine fibroids; and here I believe that the resistance of the body between the external electrode on the abdomen and the sound in the uterus or needle in the substance of a uterine tumour will not often, if ever, reach 500 ohms, although in one of the cases operated on by Dr. Keith it amounted to nearly 350. The practical importance of this will be seen, and the relation it bears to the size and quality of the cells one has to get, by a short reference to the battery we are using at present. It consists of twenty-four large Leclanché cells, whose united electromotive force when joined in series is nearly 36 volts, and whose internal resistance is 12 ohms. When an external resistance of 500 ohms is added to this, and the calculation made, we have, according to Ohm's law, which, when C = current, E = electromotive force, R = external resistance, and R' = internal resistance, is expressible thus: $C : \frac{E}{R+R'} : \frac{36}{500+12} = 70$ milliampères. With an external resistance of 350 ohms a current of 100 milliampères can be got; but to reach to even 100 milliampères with 500 ohms of external resistance eleven cells would have to be added to the battery of twenty-four. The M. F. of each cell has been, for convenience, taken at 1·5, instead of 1·48. I am, Sirs, yours faithfully,

Edinburgh, Aug. 3rd, 1887. SKENE KEITH.

PANSLAVISM IN RUSSIAN UNIVERSITIES.

THE alleged Russianising of the Germano-Russian schools, particularly in the Baltic provinces, is, it happily appears, without foundation. Dr. Schultze, sometime clinical lecturer at Heidelberg, who had been invited to fill a corresponding chair in the University of Dorpat by the Russian Government, has since been unconditionally confirmed in the post, without his being required to prelect in the Russian language. Prof. A. Schmidt, also of Heidelberg—"Blut Schmidt," as his colleagues pleasantly distinguish him, in allusion to his most considerable scientific work—and now Rector of Dorpat University, characterises as "pure fable" the report that restrictions, in a Panslavic sense, are imposed on the German occupants of Russian chairs.

Dr. W. Budd (Exeter).—The paper has been received and will appear shortly.

"THE THROAT AND ITS DISEASES."

To the Editors of THE LANCET.

SIRS,—A very serious error having been brought under my notice by a purchaser of the recently published second edition of my book, "The Throat and its Diseases," I shall be obliged if you will allow me to correct it in your columns, for the sake of those who might otherwise overlook the mistake. In formula 80, page 568, a drachm of sulphate of atropia is ordered to an ounce of vaseline as an application to the nostril. It should, of course, be a drachm of the *solution* of that alkaloid. Thanking you in advance for your courtesy, I am, Sirs, yours truly,

Weymouth-st., Portland-place, Aug. 17th. LENNOX BROWNE.

JOSHUA INGHAM IKIN, F.R.C.S.

Died August 8th, 1887.

IN MEMORIAM.

Shall it be said, alas! he died too soon
Whose life's good work completed is on earth;
Have we not that to which himself gave birth
Long years ago?—the consecrated boon
To sick and poor;—the sunshine of that day
When up the garden path he passed along
With Carlisle at his side, and spirit gay,
And heart all mirthful as the free bird's song
'Mid leafy, sighing woman, that holy house did rear
For you and your fond little ones so dear.

August, 1887. A. T. G. LITTLEJOHN FORTUNE.

THE NATURE AND TREATMENT OF EPISTAXIS.

THE central idea running through the suggestive paper contributed by Dr. Harkin to the Therapeutical Section of the British Medical Association at its recent meeting in Dublin is lucid enough; but, like many clever theories, it requires more proof than we think the author has adduced in the paper. Again, that important hæmapoietic viscus, the liver, is brought into requisition as the chief cause of various, chiefly chronic, blood states in which epistaxis—and, we may add, other hæmorrhages—are prone to occur. Epistaxis may occur under a variety of conditions, and the blood may be hypinotic or hyperinotic, anæmic or plethoric, or even, it is possible, possessing the right number of red blood-discs; but whatever the condition of the blood, Dr. Harkin believes that much good may result from treatment directed to leading the erring liver back to normal modes of action. The quality of the blood may be improved, and the equilibrium between its solid and fluid constituents may be restored, "by the free administration of chlorate of potassium alone, or combined with a soluble salt of iron." The health of the liver may be improved by counter-irritation over the region of the liver, a large blister being in practice the most convenient and suitable application. Dr. Harkin strongly deprecates active surgical interference with the diseased liver or its portal tributaries.

Cymro.—For registration on the ground of having been in practice before the passing of the Dentists' Act it is necessary that information of the claimant's name and address, &c., should have been transmitted to the Registrar before Aug. 1st, 1879.

A. B. C.—We do not give medical advice.

SWEATING OF THE FEET.

To the Editors of THE LANCET.

SIRS,—Many persons during the hot weather are subject to very great discomfort in consequence of an offensive odour proceeding from the feet. For this cause a servant has been discharged from her situation, a gentleman has been debarred from frequenting society, and hitherto no antidote has been found for the evil. In a case, however, which has come under my notice I have found a remedy in the use of soda; so much so that by an effectual daily application of it the nuisance has been entirely removed, whereas by one day's omission the nuisance has recurred. I have not tried ammonia, the stronger alkali, but feel confident that if the soda be applied either in fine powder or concentrated solution, as the skin will bear it, the remedy will be effectual, and be found a great boon to persons so afflicted.

I am, Sirs, yours very truly,

Newhaven, Aug. 5th, 1887. D. RICHARDSON, M.R.C.S., L.S.A.

CAUCASIAN WATERING PLACES.

THE Caucasian watering places or mineral baths seem to be well patronised this season, no less than 4636 persons having taken tickets up to July 2nd, in addition to a certain number of officers and civil servants who are sent there at the public expense, as well as seventy-four persons whose expenses are defrayed by different charitable institutions. There are this year sixty medical men in practice at the different "baths."

D. D. Jones, M.B.—We think any of the leading firms of instrument makers will undertake the work.

HOME FOR IMBECILES OF LIMITED MEANS.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if any of your readers can tell me of any Home that would receive a man of weak intellect, brother of a working farmer, about forty years of age. He is a good and capable worker, and his friends simply seek to place him under restraint in consequence of his constantly straying from home, often being heard of at long distances in a most abject condition. The friends could pay about ten shillings a week towards his support. Any information on the subject would be thankfully received.—Yours truly,

Aug. 14th, 1887. B. FARADAY GILES, M.D.

SANDALWOOD IN BLENNORRHAGIA.

M. C.—The oil of sandalwood in the treatment of gonorrhœa (blennorrhagia), both in its acute stage and in some of its sequelæ, has been found efficacious by Posner, Letzel, and Casper, and more recently by Rosenberg, of the Jewish Hospital in Berlin. In chronic blennorrhagia, this last named investigator has not been equally successful. Cystitis and prostatitis were among the sequelæ in which he found its use beneficial.

A CASE-BOOK.

R. F. W.—There is room for a few good forms of case-book. One such is before us for practitioners and students which would meet the views of our correspondent—Lewis's Pocket Case-book, designed by A. T. Brand, M.D., to be had of H. K. Lewis, Gower-street. It is neatly arranged, portable, and on good paper.

C. D.—The paper will appear in an early number.

A Volunteer Surgeon.—No.

Lectures
ON
PRACTICAL LEGAL MEDICINE.

Being the Post-Graduate Course delivered at St. Mary's Hospital,

BY AUGUSTUS J. PEPPER, M.S. LOND.,
LATE EXAMINER IN FORENSIC MEDICINE TO THE UNIVERSITY OF LONDON.

LECTURE I.

GENTLEMEN,—In a short course of four lectures it would be impossible for me to go deeply into the wide subject of legal medicine, nor would any good purpose be served by a general survey of the theoretical aspects of the question. I have chosen, therefore, to bring before you such lessons as I have learnt from practical study, and to present them to you with a hope that they may at least serve you in good stead in your own future investigations. It has often surprised me how good common sense has saved a man from making the most grievous blunders whilst instituting inquiry into problems complicated, and therefore difficult. We learn most by our mistakes, and I want you to see the occasion on which those mistakes are likely to be made.

My first lecture will treat chiefly of Inquest Practice—that department of forensic medicine in which all of you are certain at some time or other to be personally engaged. A coroner's inquisition must be held *super visum corporis*—that is, "if there be no view, the inquisition is void." It becomes, then, the paramount duty of medical men to do all in their power to bring cases in which the cause of death is unknown before the notice of the coroner, who will decide upon the information laid whether an inquest be necessary. If the cause of death is unknown, the deceased may have died directly or remotely from some form of violence. In such cases an inquest must be held to determine when, where, and by what means the death happened. The 27th regulation for house-surgeons at this hospital runs as follows: "The house-surgeon shall take care that any death resulting, however remotely, from accidental injury or violence be reported to the coroner immediately." Do not be persuaded, either by the importunity of others or through want of confidence as to the correctness of your own diagnosis and treatment, in a case that has proved fatal, to give a certificate of death, unless, "to the best of your belief," you are certifying that which a coroner's jury would in all probability find to be true. It would be infinitely better to be found wrong in an opinion honestly given than to lay yourself open to the charge of an attempt to evade legal process. A great scandal would arise if exhumation of a body were ordered in consequence of a medical man having carelessly, recklessly, or fraudulently given a death certificate. Whilst speaking of exhumation, I may say that a coroner has power to order the disinterment of a body "privately and secretly buried," and where the deceased person "died not of a natural but a violent death." He can also do it if the burial has inadvertently taken place. Only last month such a mishap occurred. A woman was certified to have died from "chronic lead poisoning," and was buried in the ordinary way. The death having arisen from unnatural causes, exhumation was imperatively demanded in order that an inquest might be held. If the interment has been made in compliance with the terms of the statute, the order for exhumation rests with the Home Secretary.

A few words concerning insurance against accidents and the duties of medical men relative thereto. If a person insured against death from accident dies from an injury within the time specified in the policy of insurance, his representatives can of course claim compensation. Now, inasmuch as the policies of some insurance companies contain a proviso that the claim cannot be sustained if the death be due "wholly or in part" to disease having no causal relation to the accident—even if such disease be but the result of natural decay,—you will see at once that damages could not be recovered in the majority of cases unless on appeal a superior court were to decide that the aforesaid proviso was *ultra vires*, and therefore not binding. I say in the majority of cases; for I believe that most people killed by accident are the subjects of some organic disease, active or degenerative, incipient or pronounced; and obviously certain injuries—e.g., a severe concussion or strain—would most likely tell with maximum severity on the weakest spot. A man with fatty heart would die from syncope; a second, with atheroma of the cerebral arteries, from apoplexy; and a third, with a thin-walled sacculus of the bladder, from peritonitis consequent on rupture; and yet such might, save for the accident, have reached the natural term of life. Do not imagine I am romancing; such cases are matter of history. You will agree with me that it is highly important to make a post-mortem examination as early as possible to determine what is due to accident and what to disease. As medical men, it would be well for you, on the death of a patient, to ask the relatives if the deceased's life was insured, and if so to impress upon them the advisability of at once communicating the facts to the insurance company, and to inform them of the time and place of the necropsy and inquest, so that they may send a representative if they think fit. Were these measures systematically executed many cases of litigation would be avoided.

I need scarcely say that where a claim for compensation is made the person conducting the post-mortem examination should minutely observe all the organs and tissues, and at once reduce to writing the results of such observation. At the inquest he must be extremely careful in describing pathological signs and in correlating them. Especially must he take care not to confound the causes of death with the modes of dying. Let me give an example: In all forms of asphyxial death the organs will be found congested, but it would be incorrect to say that congestion of this or that organ was the cause of death, as such a statement would be too exclusive, and might be seized upon by counsel to prove that an alleged injury was not the *causa causans* of the death. The general practitioner will not think me presumptuous when I advise him to be fortified in these matters by the aid of an experienced pathologist. It is one thing to make a careful observation and collection of facts, and another to make logical inferences from the same. On one occasion I heard a witness depose that the body of a man unknown, who was found drowned, was that of a lunatic, because the brain was congested. He based his conclusion on the fact that he had seen the brains of six persons who had died insane, and they were all congested.

The importance of giving accurate evidence as to fact and opinion at the inquest may reach beyond the present inquiry. A criminal charge may arise out of the finding of the jury, and a coroner can be compelled to produce the depositions at the trial. As regards civil actions he can do as he pleases, for in that case they are his sole property, but a copy can sometimes be obtained for a monetary consideration. Your evidence given at the inquest, then, may be dissected in another court, and, to say the least, it would be inconvenient to have to amend it there. Concerning the advisability of insisting upon making a post-mortem examination in cases where the cause of death is at all doubtful, I believe the medical practitioner can claim it as a right, and is in duty bound to decline to give a certificate of death, or state an opinion equivalent to the same before the coroner, if he has any reasonable doubt that justice will not be satisfied without the information obtainable from a necropsy. But there are cases, for example, where a man is killed by a buffer accident, in which it would be blameworthy if a medical man refused to assist at the inquisition unless he is allowed to make a post-mortem examination. He may not be able to swear to the proximate cause of death, but this does not matter so long as the main question is decided how the death was compassed. It is true that the coroner has the power, if he so wills, to order a post-mortem in every case of death within his jurisdiction; but he is accountable to the magistrates for his expenditure of funds raised by the public rates, and it would be an abuse of his prerogative were he to use it to the full. A coroner is by virtue of his election a magistrate of the peace, and not seldom he has to exercise his double function.

Wherever the reputation of a medical man or the character or freedom of any person is at stake, no inquisition can be complete without a post-mortem examination. The merest suspicion of culpability is sufficient warrant for the coroner to insist on such examination. Let me quote you two cases by way of illustration. In August, 1885, a child suffering

Digitized by Google

from shortness of breath was taken to a private surgery. The doctor on duty gave the patient a draught. Soon afterwards fatal asphyxia supervened. The father insisted that his child had been poisoned by the draught; but on examination I found that an abscess of the bronchial glands had burst into the trachea, and a quantity of caseous matter had caused suffocation. The inquest in the second case was held on December 10th, 1886. A man was charged with causing the death of a boy by striking him on the head, but the house surgeon at the London Hospital deposed that the cause of death was pyæmia from suppuration of the middle ear. The boy was said to have enjoyed robust health until he received the alleged injury, although on inquiry it transpired that there had been discharge from the ear for twelve years. I have known many such cases, and believe they are far from rare. I advise you, if you come across a case of pyæmia of doubtful origin or of cerebral abscess, to examine carefully the petro-mastoid bone. I have already spoken of the desirability of conducting post-mortem examinations early. This is especially important where a volatile poison is suspected to have been taken or administered. It is generally understood that in such cases the chances of detection of the poison become remote after the lapse of a few hours. It is true the odour quickly vanishes from the room, or even from the body, and yet sufficient poison may remain in the blood for a complete analysis. Some years ago I proved the truth of this assertion, for on the third day from the death I was able to identify prussic acid in blood taken from the heart, both by its smell and by chemical experiment. If you suspect prussic acid poisoning, take with you a clean glass plate and a solution of nitrate of silver, moisten the plate with the solution and hold the wet surface over (but not in contact with) the natural fluids of the body *in situ*—for example, the blood, urine, and the cerebro-spinal fluid in the lateral ventricles.

I will now discuss certain physical signs the subject of almost daily inquiry in the police courts and before the coroner. Medical men are required to interpret the value of these signs from a medico-legal standpoint. I refer especially to (1) *scalp wounds*, (2) *bruises*, and (3) *general emaciation*.

I have shuddered inwardly when I have read in the newspaper reports that Dr. So-and-so testified that certain linear *scalp wounds* must have been inflicted by sharp instruments. The mistake is a very common one, but none the less grave for that. Now if you consider that a blunt instrument such as a rolling-pin or kerbstone striking the cranial vertex may expand its force in a linear direction on account of the curvature of the bones, you will understand how the wound may on a cursory examination seem to be an incised one. Close inspection will reveal that the divided vessels are torn, and *not* cut. Suppose for a moment that a man is seen to threaten another with a knife, and in the struggle that ensues a linear scalp wound is inflicted, the presumption would be that the knife had made the wound, and yet from what I have just said you will see that it is quite possible such might not be the case; the distinction on surgical grounds might not be of much importance, but to the accused it would probably mean the difference of between a short term of imprisonment and penal servitude.

The subject of *bruises* is a very complex one. You will be asked to say regarding a certain bruise the mode of infliction, the amount of force used, and the approximate age. The first of these questions calls for no special comment, for unless there is something definite in the shape of the bruise you could only give a very guarded opinion. As regards *the force employed*, there is ample scope for careful inquiry. Other things being equal, the extent of the bruise will vary as the violence which caused it; but there are many disturbing influences. A very slight blow over a bony prominence may cause a very large bruise; on the contrary, if the part struck is resilient, fatal injuries may be inflicted on the deeper structures whilst the skin appears untouched. In one instance a man had been run over by a drag; death was almost instantaneous; the aorta and vena cava were severed, and yet the elastic abdominal wall was free from any bruise whatever. I have met with several similar cases. Bruises on the surface of the body are often made the basis of a charge in the police courts, and require interpretation before a coroner. I believe that many accused persons are convicted of serious assaults on the ground that the complainant bears bruises which from their extent are considered to be indicative of considerable violence. Medical evidence is called by the prosecution to throw light on this difficult question, and it *is* a difficult one. Very slight force suffices to produce a bruise of the skin in persons who lead a sedentary life; in those who are subject to privation; in those accustomed to abuse of alcohol; in individuals whose vessels are weak or diseased, from whatever cause—for example, hæmophilia, senile decay of arteries, and varicosity of veins. When required to state an opinion on the question of bruises, if you feel confident, speak dogmatically, but if you are doubtful, do not be afraid to express your doubt simply because the vulgar may read your uncertainty as unpardonable ignorance. The *duration* of a bruise varies within wide limits; an ordinary black eye will pass through its colour changes in from ten days to three weeks; but then you must bear in mind that the tissues of the face are extremely vascular, and the circulation active—conditions favourable to the absorption of extravasated blood. In December, 1886, I examined a bruise which had been made eleven days previously; it was in the leg of a woman who had died from erysipelas, and whose saphenous vein and its tributaries were much varicosed. It appeared as though quite recent, except for a faint greenish-yellow tint at its margin; slowness of the colour change and absorption was explained by the hampered state of the circulation, and perhaps also by the vitiated condition of the blood. The legal bearing of the age of a bruise may be very important, and this is my reason for so pointedly directing your notice to it. I have not seen it mentioned in books that a bruise in the cadaver, which at first is bluish-black in colour, may, if quite superficial, become pink—in fact, almost scarlet; but such is the case. At first sight the appearance would seem to indicate a recent extravasation of arterial blood. I believe it is because the blood, being close to the surface, gets oxidised. A case in point came under my notice at an inquest at South Hornsey in September of last year. My note runs thus: "There was a bruise on the left of the umbilicus as large as the palm of the hand; it was bright-red at the centre, and purple at the margin; clearly quite recent."

The police and coroners' courts have not infrequently to inquire into cases of supposed or even alleged *starvation* of *young children*; and I know of no subject more heavily taxing the judgment of medical men for their proper elucidation. A child may die from inanition from one of three primary causes—(1) for want of sufficient food, (2) on account of improper quality of food, and (3) from defective assimilation owing to natural disease. The second of these factors is without doubt the most frequent. Infant mortality from improper feeding is something appalling. In the majority of instances it is owing to ignorance, and not negligence or culpability. A child may be given more than sufficient for sustenance and growth, and yet die from general wasting, the indigestible food setting up diarrhœa and vomiting; intestinal catarrh is established, and in the wake of this the mesenteric glands become enlarged; the lymph paths are obstructed, and the blood-making function seriously disturbed. On the other hand, tabes mesenterica may arise as an idiopathic affection. After careful investigation of many cases of chronic starvation, I have come to the conclusion that there are no *certain* pathological signs by which a medical man can decide whether a child has succumbed to starvation from natural disease, misadventure, or wilful neglect. All he can say is that a given hypothesis is or is not consistent with the facts, the true interpretation being made chiefly from collateral evidence. The older the child, the more probable becomes the theory of criminal intent on the part of those whose duty it is to supply it with food of proper quantity and quality. A number of bruises or other injuries on the body of a child greatly emaciated would be presumptive evidence of culpable neglect as regards the wasting, but obviously even here the greatest caution must be exercised by the medical man. Let him give his opinion clearly, but guardedly. In March, 1886, a woman was committed for trial at the Old Bailey for criminally neglecting her child. The case was investigated before the coroner and at the police court. The grand jury threw out the bill after hearing from me the evidence I had given at the preliminary inquiries.

There is one thing more I must draw your attention to to-day. Persons are not unfrequently found in a delirious or unconscious condition in the streets. Naturally, but unjustifiably, the police are in the habit of attributing the symptoms to drink. Now, either as divisional surgeons or

Digitized by Google

in your general practice, you will be asked to make a diagnosis in these cases. It may be that you will have no difficulty in discerning between alcoholism and other forms of illness, such as apoplexy, uræmic coma, epilepsy, &c.; but experience teaches that it is only too easy to make a mistake, and therefore I advise you, if you have the slightest doubt in the matter, to keep or order the case to be kept under medical supervision. A few hours will suffice to clear up the uncertainty. This advice applies with double force to the medical officers of public institutions like hospitals and workhouse infirmaries. The public look with a jealous eye upon the management of places they are asked to support, and there is a tendency to presuppose abuses of offices of trust. It would be a grievous mischance if a house surgeon were, after dressing a scalp wound of a person partially insensible from apparent drunkenness, to restore him to the care of the police, and afterwards to find at an inquest that the case was one of apoplexy. Several such mistakes have occurred to my knowledge. I would not be hard on my professional brethren, but I cannot help thinking a certain amount of opprobrium for these errors is not altogether unmerited.

ON THE

NATURE AND TREATMENT OF HYPERTROPHIES AND TUMOURS OF THE NASAL AND PHARYNGEAL CAVITIES.[1]

BY J. L. W. THUDICHUM, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE QUEEN'S JUBILEE HOSPITAL.

DURING the last twenty years the knowledge of diseases of the nasal cavity and the methods of their treatment have been so much improved that they are not behind any other branch of surgery or medicine. The operative, particularly the electro-caustic methods, vie in accuracy with operations on the eye, and the results, as deduced from comparative scientific discussion, have been eminently satisfactory. This has been acknowledged by many members of the profession, notably by those, not a small number, who placed themselves under my care for troubles belonging to the category here to be considered. One of the commonest ailments is hypertrophy of one or other or both of the lower turbinated bodies. This affects most commonly the anterior part, and is not rarely so great as to close the nostril. It then leads to respiratory (nasal) inadequacy, and severe consequences to lungs, nerves, and constitution; it conduces to malformation of the septum from unequal pressure, and from bilateral pressure and ulceration to perforation and loss of the septum.

CASE 1.—A married woman, from Bradford, came under my care on Nov. 9th, 1886. Her nose had gradually become narrow, and entirely obstructed in 1885. On inspection the nose was found to be closed by the two hypertrophied turbinated bodies, which admitted only a probe, no speculum. I effected ablation of the bodies by electro-cautery. When about an inch of the right turbinated body had been removed, it was seen that the septum was perforated and extensively ulcerated all round the perforation. The left concha was now also shortened, and a completely sufficient passage through each nostril was established. The patient was placed under suitable treatment, and when I saw her on Feb. 1st, 1887, she had completely recovered the faculty of respiration through the nose with closed lips, had lost the nasal speech, recovered her sense of smell, and the ulceration was nearly healed.

CASE 2.—A gentleman, residing at Leeds, received a blow on the nose by a door. The nose bled inside and out, and was swollen. He then had inflammation in the ethmoid region with severe pain during five days, after which an abscess discharged into the nose. (This was surmised to be caused by a bad tooth, which was drawn without result.) This discharge and inflammation continuing, polypi formed, and at last the patient came under my care. After preliminary removal of some polypi on Oct. 5th, 1886, both lower and middle right turbinated bodies were found greatly hypertrophied. The only respiratory passage was underneath the lower turbinated body, and this was liable to be blocked by the slightest cold or irritation. I therefore removed on Oct. 15th, 1886, ten days after the operation for polypus, the anterior part of the lower turbinated body. This produced an adequate respiratory canal, and the parts healed well. During the operation a relatively large quantity of pus was discharged from the ethmoid region, and it was necessary to deal with the parts in which the pus originated. On exploration some dead bone was found in the labyrinth and removed. By continued treatment the swelling diminished, and it could be ascertained that the middle turbinated body was enlarged to a bulla, filled with pus. I therefore cut away this bulla entirely by electro-cautery, and cleared the septum from adhesions up to the cribrous plate. Now the abscesses in the ethmoid cells—i.e., the labyrinth—were all laid open and discharged; the anterior and posterior healed quickly; the middle one persisted to discharge in a variable manner. The cavity could be explored with probe, and cleared with sponge. The patient was under treatment about six weeks, and left for his home almost entirely recovered, and well satisfied with his freedom of breathing.

Fracture of the anterior parts of the nose produces sometimes a distortion of the septum, which closes the nostril entirely, and may be mistaken for hypertrophied turbinated bones.

CASE 3.—Master J. K—— came under my observation with the results of this accident. I advised an early operation for this deformity, which, as all experience shows, will no doubt increase.

CASE 4.—A clergyman had suffered for several years from obstructed nose, and been operated upon for polypus by forceps a great many times. He had been asthmatic and was constantly hoarse, and fairly unable to attend to business. I removed a great number of deep-seated polypi from both sides, and obtained a good passage for the right nostril only. The left remained obstructed by a posterior growth which could not be reached owing to hypertrophy of the lower turbinated body and of the septum opposite. I therefore removed, eight days after the first operation, the greater part of the left lower turbinated body, also the ridge from the septum, both with electro-cautery. When the patient blew through the nostril forward it became completely blocked; when he drew backwards it was quite free. The obstruction was an old, hard, strongly-attached, but movable polypus, which was seized, looped, and removed by electro-cautery. The operation was perfectly successful, and after some general treatment the patient resumed his duties, with nose and vocal organs perfectly restored.

CASE 5.—A gentleman, aged twenty-four, was introduced to me by Mr. Tegart. He had been much treated by powders, lotions, and other means, douche, &c., for a discharge from the right nostril, but without effect. The right lower turbinated bone was greatly hypertrophied and pressed the septum in a deep excavation to the left. In the left nostril the septum was hypertrophied below. On July 9th I removed the right anterior lower turbinated body by electro-cautery, also the excrescence from the septum in the left meatus. The results of the operation (at which Mr. Tegart was present) and of the after-treatment were excellent.

CASE 6.—An officer of Cuirassiers in the German army, came to London to be under my care in the course of the summer of 1886. He had for some years suffered from nasal obstruction, which had so altered the sound of his voice as to greatly interfere with his efficiency as a commander. He had been under the care successively of three so-called specialists in Germany, and had in the aggregate been burned with the electro-cautery, superficially, over the lower turbinated body, more than forty times. He had been further tortured with attempts at dilatation of the nostril by the introduction of hard sticks of laminaria. This most painful treatment had the effect of producing a series of asthmatic attacks, of which some were dangerously severe. On examination I found the right meatus very narrow and contracted, the membranous part of the turbinated body scarred and contracted, but the posterior part hypertrophied, osseous, and touching the septum, which was itself hypertrophied and kinked towards the turbinated body. I effected removal of the hypertrophied part of the turbinated body and ablation of the prominence of the septum. The

[1] Abridgment of a paper read before the West London Medico-Chirurgical Society, Feb. 4th, 1887.

Digitized by Google

patient declared that the operation gave him complete and absolute relief; he lost the nasal tone of his voice completely, and was at once, and has ever since remained, free from all symptoms of asthma. Having in the autumn of 1886 passed, during two months, through the most active part of the manœuvres of the German army, he observed some respiratory inadequacy in his left nasal meatus. He therefore came to London in the spring of the present year to have the left meatus operated upon in the same manner as the right one had been. The effect was as satisfactory as that of the previous operation, and the patient is now restored to perfect health and efficiency, and is sense of smell is rather more acute than it was before the operation, and is in every sense complete.

CASE 7.—An Irish gentleman and landowner, aged forty-three, who had been suffering for twenty-three years, and had been operated on twice ineffectually, applied to me for treatment. I removed from each nostril a number of grotesque polypi; and from each a large ampulla, with many polypi attached, being the dependent part of the middle turbinated body. In this case both the respiratory and olfactory meati were reestablished in eight days, and the patient made a perfect recovery.

CASE 8.—A young gentleman, aged twenty-three, from the west of England, had suffered for six years, had endured two unsuccessful attempts at operation, and used much iodine in glycerine as a paint to the inside of the nose. The ethmoid region contained many polypi, and both middle conchæ were much hypertrophied and covered with outgrowths; the septum was bent to the left and thickened in left and right meati on prominent parts. I removed both upper turbinated bodies and all polypi, and restored to the patient a more comfortable breathing passage than he had ever had before. This was the more important for him, as his local trouble was no doubt caused by an inherited tuberculous diathesis, which had already invaded the right lung. The patient resided during the winter in Malta.

CASE 9.—This case was that of a girl, aged four years and a half, whom I saw in consultation with Mr. Cripps Lawrence. Both lower turbinated bodies were enormously enlarged and pressed the septum in the opposite direction. There were also enormously enlarged tonsils. In this case a plan of treatment was adopted to reduce the hypertrophy by medicine. Such cases are frequent, and rarely admit of operation in the nose before the patients are of nearly adult age.

CASE 10.—A clergyman from the country had suffered for many years from obstruction in the nose, and had been operated on many times without much advantage. After clearing away some polypi, I found an enormously enlarged right turbinated body. This I removed entire, as it not only obstructed its own meatus, but the left one also by pressure upon the septum. When the bulla was cut through, pus escaped, and it was now seen that the entire swelling was, in fact, an encapsuled abscess. This case is further remarkable on account of a variety of nervous symptoms, which disappeared entirely after the operation: cerebral confusion with hemianopsia, beginning of spasmodic fits without loss of consciousness, and spasm of the pylorus. The etiology pointed to measles as the first cause of the chronic illness. The patient is now practically well.

These cases are a sufficient support of the thesis—which I could sustain by a very large experience—that in cases of chronic hypertrophy of any of the four (lower) turbinated bodies, causing obstruction or accompanying neuroses, ablation is indicated, and is in most cases the only means of effecting a cure. I have experience of cases which have remained well for ten and fifteen years. Not a few patients, having had relief in one nostril, came after a period to obtain the same relief in the other, as did the patient in Case 6. These cases demonstrate that to call such operations either unnecessary or unjustifiable, and their result a mutilation, is not only contrary to common sense but to actual fact; for these persons were mutilated by their disease, and restored to health by the operation.

The reflex neuroses caused by nasal and naso-pharyngeal disease have engaged my attention and been treated in my publications since 1865. They are spasmodic sneezing, lacrymation, asthma of various forms, hemianopsia, convulsive twitchings, mydriasis, spasm of pylorus, vertigo of such intensity that the patient may fall in a semi-conscious state, disordered sense of smell (a condition which causes to the patient olfactory delusions), and others. In such cases German and American specialists have practised superficial cauterisation in the nasal cavity, frequently with such evil effects as were described at the International Medical Congress in London six years ago. In opposition to these surface cauterisations, the result of which is so well illustrated in Case 6, I maintain that if a diseased or hypertrophied part of the nasal cavity can reasonably be supposed to be the exciting cause of any reflex neurosis, it should be removed by abscission. I say exciting cause, for they are but rarely the absolute cause. For most so-called reflex neuroses, said to be, and apparently being, connected with nose disease, are only partially so or in a certain sense—that is to say, both nose disease and neurosis or nerve complaint have a common dyscratic origin, tuberculous, scrofulous, enthetic, scarlatinous, morbillar, variolar; and without such a constitutional (in the last three cases sequelar) basis the reflexes are never produced. That the local disease acts as an exciting cause is proved by the disappearance or mitigation of the neurosis after the removal of the local disease. This local disease must, of course, be clearly and unmistakably developed. To burn a healthy concha because a person is liable to asthma is more likely to provoke and aggravate, or, as in Case 6, to literally produce, than to heal it. Indeed, this surface burning in the nose, which has been so much abused, particularly in Germany, is already being found out, and some of its admirers in this country now admit that "it was calculated to raise expectations which are likely to remain unfulfilled."

I must again point out the superiority of the electro-caustic over any other method of operating in these cases. A battery of seven large Grove cells with platinum plates, an oxyhydrogen lime-light, a complete special armamentarium with best platinum wire, and a good assistant are indispensable. What becomes of cases in which the condition laid down by large experience are left unfulfilled can be seen by the following records.

CASE 11.—A young woman, aged twenty-three, suffering from multiple polypi, was treated in a country hospital for eighteen months as an out-patient. The polypi were attacked with forceps at first once a week, later on once a fortnight. No passage was ever produced, and the patient went to a London special hospital. In this she remained as an in-patient during four periods of three months each, spending the intervals necessitated by the rules in a convalescent home. Thus this patient had been under treatment for two years and a half, and had the forceps in her nose an unknown number of times—on at least 200 occasions. This person was freed from her polypi by my method in two sittings, and has now returned to service quite recovered.

That the instrument ordinarily termed a "snare" may become a delusion the following case will clearly show:—

CASE 12.—A gentleman had been suffering from polypus in the nose for several years, and had much hemicrania; he had partially lost his sense of smell, but he could recognise oil of aniseed and tincture of camphor, though he could not distinguish other tinctures, or Barbadoes aloes, or extract of conia. He had been operated upon, but almost unsuccessfully, only some pieces of tissue being removed. I found the right meatus filled with growth and hypertrophy. I removed all polypi, also a bulla, or enlarged dependent hollow lamina of the middle turbinated bone. Only after this was I able to diagnose and remove a posterior naso-pharyngeal polypus more than an inch long; after that a racemose polypus from a cellule of the labyrinth and an abnormal cavity below was removed; upon this the cellulæ of the labyrinth discharged much thick pus. The removal of the last two polypi met with an unexpected difficulty. I felt something metallic, which I seized with a hook and a parallel forceps, and found it to be a piece of iron wire two inches in length. This had probably been in the nose eight months, or since the last operation with the snare; at least the patient, a considerate, calm, educated man, had no other means of accounting for its presence. The large posterior polypus was cystic, lost its serum when opened, and collapsed, and when refilled with water had the size of an inch of a man's little finger.

Cocaine hydrochlorate in the form of a watery solution of 25 per cent. strength, used as a spray, has been of great service in preventing or diminishing local pain during these operations. General anæsthesia frequently compromises the success of nasal and pharyngeal operations, and should be avoided.

CASE 13.—A patient had been operated upon for polypus by the aid of the forceps frequently, and had been under

Digitized by Google

anæsthesia by chloroform for this purpose, as he stated, at least thirty times. Yet he had never been liberated, and his nostrils were filled with polypi. From these he was freed by electro-cautery, preceded by cocaine, in two sittings. Only very short operations in the anterior part of the nasal cavity can be safely or successfully undertaken while the patient is under the influence of general anæsthetics.

NOTES ON STERILITY.

BY JAMES OLIVER, M.D., F.R.S. EDIN., M.R.C.P. LOND.

EVERY occurrence in nature is the result of some pre-existing influence. The former we have agreed to call the effect, whilst the latter is called the cause. Nothing is accomplished by a sudden act of transition; Nature never executes her workings by fits and starts, although this may at times appear to happen. Interdependence is ever avowedly maintained. In the animal kingdom especially are these facts revealed, whether the end attained be one likely to prove beneficial to or exert a prejudicial influence on the species. In the whole organic world change is wont to be gradual. Creation and destruction keep pace with each other, and wherever there is life we witness co-taneously gradual death. The process of generation manifests the same phenomenon. Between that state favourable to the production of a numerous offspring and that culminating in complete sterility there exists no distinct line of demarcation; so gradually, in fact, do the two states glide into each other that we are wholly unable to say where the one ends and the other begins. In the vegetable and animal kingdoms alike we encounter every degree of fertility.

The reproductive function, no matter how fulfilled, is wrapped in obscurity, and full of the greatest complexity, yet from a scientific point of view teems with questions of the deepest interest. Take, for example, the well-known yet mysterious influence of a first coitus on the progeny resulting from several succeeding sexual congresses. A purely-bred Arabian mare was covered by a quagga, the offspring resulting therefrom being a hybrid. Never afterwards did the quagga have an opportunity of covering this mare, yet each succeeding progeny, although begotten by an Arabian black horse, continued for some time thereafter to evince characteristics of the quagga, the hair of the mane especially being like that of the quagga, short and stiff. In this case the first coitus affected in a most marked and wholly inexplicable manner the offspring of the Arabian black horse. So potent may a single fertile coitus prove to be that it may continue to exert its influence for long afterwards, and this in cases beyond all doubt. I merely adduce this evidence in support of the tenet already expressed, that the whole question of reproduction is full of complexity. In order, however, that we may, as far as possible, have a clear conception of the multifarious influences for ever at work tending to induce sterility, we must approach the subject and attempt to elucidate revealed facts with a mind free from all bias, for in this way alone shall we serve the end of science by encouraging truth. Mistakes, be it remembered, more frequently arise from lack of observation than as a result of sheer ignorance.

In man and the majority of animals, perpetuation of the species is maintained by a process of gamogenesis, by a coalition and further segmentation of the germinal elements produced by two sexually distinct individuals. This participation in the act of generation by two parents necessarily hinders us in our investigations regarding those causes which, constantly at work and liable to the greatest variation, act and react directly or indirectly on the reproductive organs. In the case of the male parent all interest actually ceases with the emission of the sperm element; whilst the female, on the other hand, not only produces the other germinal element, but must retain and nourish the impregnated ovule for a more or less definite length of time—until, in the fœtal resultant shall have reached that state of development or maturation enabling it to maintain an independent existence. An inquiry, therefore, into the causes of sterility must have regard merely with the glands concerned in the production of the germinal elements and the relative affinities of these elements for each other, but deal also with those conditions, constitutional it may be, which directly or indirectly interfere with the functions of the whole reproductive tract and the competent fulfilment of its requirements. When we remember that the female plays the all-important part and for a continued length of time in the production of offspring, it is not at all astonishing that we should so frequently find authors disposed to attribute the cause of failure in the sexual congress to become fruitful to some occult influence at work on the part of the mother. This admission does not, however, imply a need for the detection of some structural change in the organs of generation in a female who, because she has legitimately indulged in sexual intercourse for years, has never become pregnant. This, I need hardly add, is too commonly revealed, and simply as a result of defective observation. In the majority of such cases the alleged alteration in structure has no other than a mere fanciful existence in the mind of the observer himself. Let us not, therefore, be carried away too readily by a semblance of brilliant results obtained apparently by a too meddlesome interference, for careful observation teaches us that the good which follows is as a rule the outcome of an enforced sexual rest. In order that any organ of the body shall continue to perform its functions healthily, time must be allowed for the structure to regain its vigour after each period of activity. If sufficient rest be not obtained, the function becomes impaired and the structure itself may eventually undergo change because of a maintained vascular turgescence. An immoderate indulgence in sexual intercourse, or an artificial mode of gratifying the passion, tends to induce a state of sterility, and the possibility of conception is favoured by complete sexual rest followed by a moderate indulgence in the act.

In the human race there are so many factors for ever at work in the social life and habits of the individual which thwart us in our endeavours to elucidate questions bearing on the reproductive functions, that our chief information regarding those causes which tend to induce a sterile state must be obtained from facts afforded us by the whole organic world, whether it be vegetable or animal. Lately I saw a patient who, at the age of thirty-six, had given birth to her first child. Although living a marital life for eight years, she had never before been pregnant. In this case I found on interrogation the delay in conception was the result of the adoption on the part of the husband of a simple but well-known mode of protection, and this because of a mutual desire on the part of the husband and wife to be free from the cares of a family. That certain physical states occurring in the organs of generation hinder conception is apparent to everyone. They are, however, not only manifestly over-rated, but in many cases purely imaginary. Rarely, for example, if ever, do we find the lumen of the cervical canal of the uterus so narrowed in a female, otherwise reproductively healthy, as to be a fertile cause of sterility. In order that this may receive some credence, it may be well to consider the train of events consequent upon impregnation in the bird, as throwing some light upon the location at which in the reproductive tract the sperm and germ cell meet and coalesce. In birds, the egg, after fertilisation becomes coated with a calcareous product—the shell, which serves to protect the contained mass from all extraneous influences to which during the process of incubation it may chance to be exposed. This is the result of no mere acquisition on the part of the female bird, otherwise it must have foreseen the prejudicial influences to which the unprotected mass would have been exposed and have been capable of combating effectually such dangers. The secretion of this calcareous incrustation takes place in the lower and somewhat dilated portion of the oviduct, in a part comparable with that which in the human female becomes uterus. If the oviduct fails to fulfil its function in producing this chalky deposit, the unprotected mass cannot be brought to maturity, and the failure must be viewed as a degree of sterility. Prior to the deposition of the shell, however, the impregnated mass receives also an albuminous covering derived from the upper and tortuous part of the oviduct. In the case of the bird therefore, and all animals with a similar reproductive tract, the germinal elements coalesce somewhere about the free extremity of the Fallopian tube. The sperm cell in the human female travels a tube of very narrow lumen; so long therefore as the lumen of the cervical canal continues equal to that of the oviduct, it will not *per se* offer any very serious obstacle to conception.

In all animals the reproductive organs, it would appear, are highly sensitive, the most trifling changes in the habits

Digitized by Google

or surroundings serving in some occult manner to disturb their functions. In many cases dependency seems wholly incredible. Animals, for example, tamed and kept in their own country may become sterile, and this apart from any negligence in the way of food or want of attention to the general comfort of the animal on the part of those who keep them, the physical state of the animal at the same time continuing apparently unimpaired. Elephants domesticated in their native home evince this tendency, and have never been known to couple under such circumstances, although the generative organs remain functionally active. The nature of the food, it will often be noticed, exerts a prejudicial influence on the organs of generation. Mares brought up on dry food continue sterile, and only prove fertile some time after they have been turned out to grass. Under the more favourable conditions of life they gradually recover the power to procreate. Mere change in food, therefore, inappreciable though it may seem to be, may nevertheless determine a complete inertia of the reproductive organs. It has been stated that lions in travelling shows prove more prolific than those confined in zoological gardens. Why this should be so is difficult to understand, for the animals in such menageries are not better fed nor better tended than those in our gardens. It is quite possible, however, that the constant variation in surroundings, and the perpetual state of excitement induced by their movement from place to place, may account for the greater sexual vigour displayed.

In some cases domestication increases fertility, and this apparently because of a more easy access to food which is at the same time more highly nutritious and presented in greater abundance. The domestic fowl, for example, lays more eggs than any bird in the wild state. All animals, however, are not equally affected by like influences and conditions. The lion when confined breeds freely and produces a greater number at a birth than any other member of the same tribe. Under domestication the sexual appetite may remain unimpaired, and yet sterility results. The bears in the Zoological Gardens here have been seen to couple very frequently, yet congress seldom proves fruitful, for they very rarely produce young. Male birds often lose their characteristic plumage under confinement. Under such circumstances the constitutional change, manifest though it undoubtedly is, nevertheless is free from any associated enfeeblement of the reproductive power. The sexual passion may continue in abeyance without apparent reason, and without correlative change in the physical well-being. Absence of sexual passion does not, however, imply sterility, for frequently I have seen women who, experiencing no pleasure whatever during coitus, nevertheless conceive, and prove as fertile sometimes as those in whom the passion is readily excited. Multifarious and slight it would seem are the changes in the life of the animal and its surroundings which may affect in some occult and wholly incredible manner the reproductive power. Some women I have noted continue barren so long as they live in a cold and exposed district, and mere change to a warmer part of the country is all that is requisite to prove their capability of becoming mothers.

Every male and female mated is not fertile, yet each separately may be highly endowed with the power of procreation; for this same male and same female mated with another female and another male respectively may prove eminently fertile and produce a numerous offspring. The germ and sperm cell may meet and coalesce. In order, however, that an uninterrupted segmentation may ensue, they must produce by their union not a state of equilibration, but a state of molecular disturbance. If the molecular waves radiating from the two elements are too closely allied to each other, they induce a state of equilibrium, with which all vital reaction ceases and no further evolutional change becomes possible. Darkness is produced by two rays of light of equal intensity impinging into each other from opposite directions. If the opposing forces be equal, total rest will result; that is, force is spent in overcoming the other, and there is no residual force left to exert its influence. The fault [illegible] sterility may therefore be assignable to neither parent, but to both, the elements produced by both being analogous to each other. Placed under the most favourable circumstances, they fail, when they commingle, to act and react upon each other so as to produce [illegible] capability needful for further segmentation [illegible] dependent being. This form of sterility is the result of sexual incompatibility. In man we find abundant proof of the existence of this anomalous behaviour. Lately I saw a patient who, during fifteen years of marital life with her first husband, never became pregnant, yet coitus was fully accomplished and completed. At the age of forty this female married a second husband, and became a mother within the year. The same fact has been noted frequently in the case of animals, and all that is requisite to prove the reproductive capability is to change the male and female and mate them with another female and another male respectively.

Frequently we see women who apparently exhaust their whole reproductive energy in giving birth to one child, as they never afterwards conceive. The individual may note no change in her general health, the sexual functions may be as thoroughly maintained, and the congress may be as completely effected as before, yet the sterile state prevails. Barrenness, be it remembered, is wholly independent of the general health of the individual, and is frequently remarked as an association of excess of size and great luxuriance. In plants it has been noted that very high nutrition lessens materially, or may even arrest completely, the power of reproduction. Many of our trees which become most luxuriant, and bear nevertheless flowers or fruit seldom, are sometimes made more productive by cutting the roots, and thereby lessening the amount of nutrition. I have frequently remarked that women who tend to lay on fat rapidly are apt to become barren. In the majority of such cases the deposition of adipose tissue in great abundance is the result of some constitutional state of a morbid character, and sterility is surely a concomitant, and dependent upon the same cause as that inducing the obesity.

As I have already stated, the energy expended by the male in perpetuating the species is comparatively slight compared with that amount demanded of the female. Sterility, therefore, we shall find frequently results from a failure on the part of the mother to furnish a favourable nidus for the impregnated mass or to supply that amount of nourishment requisite for those evolutional changes consequent upon impregnation. The young of animals born under confinement often die early; sometimes they are born dead or even badly formed. As a rule sterility is a physiological co-association of the functionally active state of the mammary glands. This depends upon the fact that, at least for a time, these glands withdraw from the body of the mother for the maintenance of the child that amount of nourishment requisite for the activity of the reproductive glands. In the case of the milk cow, we witness an interference with this law of nature, the glands through habitual use being made to secrete milk more or less constantly and quite independently of the reproductive system. Sometimes we find women who continue to menstruate with perfect regularity during lactation, and even become pregnant whilst suckling.

Women who marry early may for a time give birth to children too rapidly, but eventually the reproductive energy begins to wane, and a state of sterility is induced, the general health of the individual, it may be, becoming impaired or evincing no sign of deterioration whatever.

Prostitutes, so long as they persist in cohabiting with a variety of males, prove sterile; yet no special mode of protection is adopted to prevent conception. This, doubtless, depends upon the fact that the various germinal elements tend to counteract each other. We witness a parallelism in the case of plants. If the pollen from one flower be placed on the stigma of another, and within a reasonable time thereafter this same stigma be fertilised with pollen obtained from a stamen belonging to the same flower, the pollen first applied is destroyed by that last applied, and neither is capable of producing the desired effect of fertilisation. Bees and ants teach us that a life of ease and idleness is that most favourable for reproduction, whilst a life of great activity predisposes to barrenness. That race which is physically as well as mentally idle, and which is at the same time well fed, is likely to prove more fertile than another race living under directly opposite conditions. Kaffir women who live chiefly upon flesh and milk are most prolific, and give birth almost as frequently to twins as to single children. Taking all the facts into consideration, there can be no doubt that the higher education of women is detrimental to the race, tending as it inevitably must to engender a state of sterility, or, what is worse, to produce a race with marked evidences of physical and mental enfeeblement.

CASE OF TETANUS FOLLOWING BURN.

EXHIBITION OF MORPHIA; RECOVERY.

BY CLEMENT DUKES, M.D., M.R.C.P. LOND.,
PHYSICIAN TO RUGBY SCHOOL, AND SENIOR PHYSICIAN TO RUGBY HOSPITAL.

ON Jan. 1st, 1887, A. H——, while sitting by the kitchen fire sewing, suddenly found her dress on fire, owing to a piece of live coal having popped out of the grate. As is usual under such circumstances, she immediately rushed out of doors, when her ignited dress burst out into a flame, and she became severely burnt on the left leg, arm, and thorax. She was brought into the St. Cross Hospital on Jan. 11th, with sores arising from burn on the left leg, knee, and thigh, and with a very large, partly sloughing, partly granulating wound, at least a foot long and four inches wide, involving the inner surface of the left arm, the axilla, and the thorax. On Jan. 21st she complained of slight stiffness of the jaw, and could not open her mouth properly. I at once prescribed some chloral, bromide of potassium, and cannabis indica; but she steadily got worse every day, slowly and surely, until she showed all the symptoms of a well-marked case of tetanus. As her symptoms became worse,—exhibiting extreme rigidity of the jaws, though they were never absolutely closed, slight opisthotonos, rigid abdominal muscles, and complete rigidity of the arm, forearm and fingers, especially on the left side,—I gave her large doses of cannabis indica, without alleviating her symptoms in the least, and without producing sleep.

While the patient was thus daily going from bad to worse, I saw a paper in THE LANCET of Jan. 22nd, 1887, by Dr. J. F. Murison, on the Value of Morphia in Tetanus, and as she could not have been much worse than she was under the treatment I was then pursuing, I immediately commenced giving her subcutaneous injections of the acetate of morphia, which I pushed as fully as I could short of killing her, and whenever I relaxed the doses, or their frequency, her symptoms became more severe. I append a record of the treatment (see Table) under which her sores healed, the tetanus disappeared, and she convalesced, until she is now (April 12th) hearty and strong. I may add that although the morphia was given so freely, there was scarcely any sleep produced, and she never once had a contracted pupil. Her aspect markedly improved after each dose, and her distress lessened, and every dose was regulated according to

TABLE SHOWING THE COURSE OF MORPHIA TREATMENT.

Date.	Drug.	Quantity per dose.	Quantity per day.	Remarks.
Jan. 21	Pot. bromide Chloral Tinct. cannab. ind.	10 grains 10 grains 7½ minims	40 grains 40 grains 30 minims	—
,, 26	Ext. cannab. ind.	¼ grain	5 grains	—
,, 31	Tinct. cannab. ind.	10 minims	4 drachms	—
Feb. 2	,, ,, ,,	15 minims	6 drachms	—
,, 3	Morph. acet., subcut.	¼ grain	¼ grain	This was given at bedtime for the first time.
,, 4	,, ,, ,,	¼ grain	1½ grains	On this day, at 9 A.M., I gave her half a grain, which made her very livid, and produced very heavy sleep and profuse cold sweats.
,, 5	,, ,, ,,	¼ grain*	2½ grains	—
,, 6	,, ,, ,,	¼ grain	2½ grains	Jerking of limbs during sleep; at times stertorous breathing.
,, 7	,, ,, ,,	¼ grain	2 grains	Scarcely any sleep; rigidity affecting the right side as well as left.
,, 8	,, ,, ,,	¼ grain	3 grains	It was found that she bore a small dose every 2 hours better than half a grain every 4 hours.
,, 9	,, ,, ,,	¼ grain	3½ grains	Necessary to give one-third of a grain every 2 hours.
,, 10	,, ,, ,,	¼ grain	4 grains	—
,, 11	,, ,, ,,	¼ grain + (5 minims, B.P.)	4½ grains	—
,, 12	,, ,, ,,	¼ grain	5¼ grains	—
,, 13	,, ,, ,,	¼ grain + (7 minims, B.P.)	6½ grains	This was the greatest quantity given in a day.
,, 14	,, ,, ,,	¼ grain + (7 minims)	5¼ grains	—
,, 15	,, ,, ,,	¼ grain + (7 minims)	4 grains	Occasionally sick from this date to the end.
,, 16	,, ,, ,,	¼ grain	3½ grains	—
,, 17	,, ,, ,,	¼ grain	3 grains	—

her symptoms. The constipation occasioned was, however, a great annoyance; her abdomen was immobile, and, owing to the condition of the muscles, felt like a board. From what I saw of the distress before the administration of morphia, and the relief afforded during its administration, I trust, if ever I should be the victim of tetanus, that I may be at once put under its influence.

TWELVE MONTHS' RECORD OF GUNSHOT INJURIES.

By C. W. MANSELL MOULLIN, M.D., F.R.C.S.,
ASSISTANT SURGEON TO THE LONDON HOSPITAL.

A. O——, twenty-four years of age, was admitted into the London Hospital on Oct. 3rd, a few hours after receiving a gunshot wound of the left forearm. A charge containing an ounce of No. 9 shot had exploded at a distance of a few feet, and the greater part had passed through his coat-sleeve and entered the flexor surface of his limb. When it was uncovered it was found to be perfectly riddled. Very few shot had entered above the elbow or below the wrist, but the whole of the space between these two joints was evenly dotted with minute openings, out of which venous blood was slowly oozing. The edges were bluish in colour and inverted; a probe was passed down a few, but in no case could the shot be felt, probably owing to the fact that the openings in the layers of fascia and the muscles no longer corresponded with those in the skin. On an average, there were three or four to every square inch; none had gone through the arm, and there were no powder grains in the skin, even of the wrist, which had not been protected by his clothes. The forearm was very much swollen and quite tense, the skin fairly warm to the touch, and though the radial artery could not be felt at the wrist, there was a certain amount of colour under the finger-nails, and it returned readily after being driven away by pressure. The pain was very severe, but it did not correspond to the distribution of any nerves; it seemed to be general, and due rather to the extreme condition of tension than to anything else. Sensation was impaired over the whole hand, though it did not appear to be actually lost anywhere except over the ball of the thumb. It was explained to him that in all probability his arm would have to be amputated, but, as he was exceedingly unwilling and was ready to run any risk, it was determined to make an attempt to save it. The whole of the injured part, which had been well sponged over and wrapped in antiseptic gauze as soon as he came into hospital, was immersed in a carbolic bath, temperature 100° F., one part in forty for the first hour and one in eighty afterwards, and it was kept soaking in this, night and day, for twenty-four hours. At the end of that time, when the part was examined, it was found to be more tense than ever, so that some incisions were made through the skin for the purpose of allowing the accumulated serum to escape; it was still warm, but after it had been out of the bath a few minutes the temperature fell very considerably, the diminution in the sensibility of the skin was more conspicuous, and the pain, in spite of repeated injections of morphia, had become almost intolerable. In twelve hours more it was quite evident that decomposition had set in, and that the part was rapidly becoming gangrenous. Sensation was completely lost; one or two incisions that were made into the subcutaneous tissue about the middle of the forearm showed that in places at least it was already sloughing; emphysematous crackling could be felt in front as high as the elbow, and on the inner side nearly up to the axilla. In spite of the undoubted putrefaction of the limb, there was no evidence as yet of any considerable degree of septic intoxication; the temperature, which the previous evening had been 100° F., had only risen a fifth of a degree; the pulse, it is true, was very rapid (120), and the respirations were hurried and shallow. But this might reasonably be laid to the credit of the extreme pain which the patient had been enduring for a day and a half. The forearm was amputated immediately below the elbow. Skin flaps were made, the longer on the dorsal surface, as that was the least injured; and the muscles and soft parts divided as high as possible. All the tissues were very dark in colour, sodden, and œdematous; but there was no actual slough along the line of the incision. There is no need to give any detailed account of the further progress of the case; the temperature rose to 102° the next morning, and then fell to 100°, about which it fluctuated for a few days before becoming normal. A small part of the dorsal flap sloughed, and about twenty or five-and-twenty shot suppurated out through the wound, but practically convalescence was uninterrupted. The limb itself was in such a condition that it was impossible to ascertain if any of the main arteries had been severed. There can be no doubt the gangrene was due to the bruising caused by the excessive number of small contused and punctured wounds, and to the extreme degree of tension set up. The circulation did not stop immediately, though pulsation could not be felt in the radial at the wrist; it was finally cut off by the effusion and swelling that followed the injury.

W. N——, aged thirty-five, was admitted on June 19th with a bullet wound of the right side of the forehead, about an inch and a half behind and a little above the external angle of the orbit. He was perfectly conscious; there was no paralysis or loss of sensation; the eyes moved normally; the pupils were equal, and, in fact, his nervous system did not seem in the least disordered. The pulse was 72, feeble and very dicrotic; respirations were 20 to the minute, and the temperature 100°F. The wound was small, only one-third of an inch in diameter, the edges inverted, and a thin stream of venous blood continued to ooze from it. A probe could be passed quite three inches into the opening through a hole in the bone, in a direction inclined slightly forwards. No brain substance was oozing from the wound, but there can be no doubt, from the direction it took, that the bullet had gone through, or at least into the substance of, the frontal lobes. No evidence of its presence could be found, so that no attempt at extraction could be made. The wound was covered over with a piece of lint dipped in lead lotion, and the patient placed in bed in a darkened corner of the ward. A few hours later the temperature had risen to 101·5°, the pulse was 42, and the right cheek had begun to swell. He had vomited blood on several occasions, and was very restless, complaining of pain extending over the whole of that side of the head and face, so that it was impossible for him to sleep. The next morning the eyelids of that side began to show staining, and blood was observed making its way gradually forward beneath the conjunctiva. The swelling of the face was somewhat less, but there was a complaint of pain on the opposite side of the head, about the highest point of the temporal ridge. Firm pressure here evidently made him flinch, but there was no sense of yielding or œdema. The further progress of the case does not need any detailed description. The swelling subsided gradually; the staining and ecchymosis slowly cleared up; the tenderness disappeared, and the wound closed in without more than a trace of suppuration. There was no sign of paralysis from first to last, and no impairment of vision. The temperature never rose higher than on the second day; the pulse rose to 70 in the minute, at which it remained fairly stationary, and the patient seemed to recover completely without the slightest loss of memory, even for the events that immediately preceded the injury. He was discharged on July 28th, apparently as well as ever he was. The bullet was fired from an ordinary seven-chambered Colt's revolver by the patient himself while standing in front of a looking-glass. Four cartridges were discharged, but nothing was known about the course taken by the other bullets. This was the only wound that he received. There can be no doubt that there was a fracture of the orbital plate of the frontal bone; and probably from the blood that was vomited the injury involved the roof of the nasal fossæ as well. The probe passed in apparently quite straight, but there is no means of telling whether the bullet was lodged in the anterior lobe of the brain on the opposite side, or whether it might not have been deflected from its course by the bones through which it passed and turned downwards into some part of the ethmoidal cells. It is very difficult to understand what can have been the cause of the exceedingly localised tenderness on the opposite side of the head. It persisted for some days, and was so intense and accurately defined as to give rise to the suspicion that the bullet had in some way passed across the brain and fractured the skull from the inner side; but as there was no œdema or sense of yielding, and as it was not quite in the line of the wound, it did not seem advisable to interfere in any way, and the case was left entirely to itself.

J. T——, aged thirty-two years, a strong healthy man, who had been a teetotaler for some years, was admitted on Jan. 12th with a gunshot wound of the foot. While out shooting, carrying his gun under his arm, one barrel went off, and the whole charge passed like a ball through an indiarubber shooting-boot he was wearing, and through his foot as well. The aperture of entry, which was about the size of a florin, was immediately over the bases of the first and second metatarsal bones; that of exit was irregular in shape and much larger, the greater part of the sole of the foot that does not touch the ground in standing being carried completely away. The wound itself was full of *débris* of bone mixed with shot, the wad from the cartridge, and portions of his boot. It was thought at first that the injury was beyond repair, and that the wisest course would be to amputate the foot at once; but as the patient was young and healthy, and as the wound was so situated that in all probability the external plantar artery had escaped, so far at least as the first part of its course was concerned, it was determined to make an attempt to save it. The heel, the ball of the great toe, and the skin on the outer side of the foot were intact, and it was thought that if the wound could be induced to heal up the contraction would restore in a certain measure the arch of the foot, and would keep the cicatrix from pressing upon the ground in standing and walking. No attempt was made to clean the wound, or to extract from it any of the shot which it contained. It was simply immersed in a carbolic bath at a temperature of 100° F., 1 part in 40 for the first two hours, and then 1 in 100, and left there. The next morning the patient had had a restless night, in spite of a hypodermic injection of morphia; the bowels had been opened freely; the pulse was only 100, and the temperature 99°. The wound was simply a mass of slough, with the ends of the tendons hanging in it, sodden and greyish-yellow, but perfectly sweet, and with only a thin red line round. This continued through the next day and the next, the wound remaining entirely unchanged, the patient's health continuing very good and there being an entire absence of fever. But then the epidermis over the rest of the foot and the part of the leg that was immersed began to show signs of giving way. It was reddened and beginning to peel off, leaving exposed a younger, softer layer extremely sensitive to the touch. Further, the urine was olive-green in colour from the absorption of carbolic acid, and a certain small amount of albumen had begun to make its appearance. The bath was accordingly changed to corrosive sublimate, 1 part in 20,000; but it was very soon found that this would not answer. The pain was so great that it was impossible to stand it for more than an hour at a time. Boracic acid was then tried, but though the carboluria disappeared and the skin ceased to be so exceedingly sensitive, this too proved unsatisfactory; the wound became offensive. Finally, the continous bath, after it had been kept up for nine days without intermission, was stopped; the foot was wrapped in lead and spirit lotion, covered over with gutta-percha tissue, and immersed for an hour each day in a corrosive sublimate bath. In this way the tendency to putrefaction was completely kept in check. The leg continued swollen and the skin very tender, but it was not more than the patient could bear. There was not the slightest fever; the temperature rarely rose to 99°F., and never but once passed it. It was extraordinary the length of time the sloughs took to separate. At first, the wound was so large that three fingers could easily have been placed in it; then, owing to the swelling of the tissues round it, contracted, so that only a probe could be passed through; but it was not until the beginning of April that the great toe began to feel firm and to sink definitely below the level of the others. The dorsal wound, as might have been expected, healed much the quickest; that on the plantar surface seemed after a time unable to contract any further, and when the patient was discharged from the hospital at the end of April was still open about the size of a shilling. At that time he could rest his weight on the foot without pain, but the amount of movement in it was very limited, and as soon as he began to walk about it swelled up and became tender. Two or three times after that minute spicules of bone worked their way out through the dorsal surface, but the wound continued to close in, and the foot and leg to become stronger, until by the end of the summer he was able to walk four or five miles without fatigue, and to go about on ladders and scaffolding as he had been wont. The wound at the end of the year, when I saw him last, was perfectly sound; the great toe was an inch shorter than its fellow; there was a high arch to the foot, the whole of the under surface of which was occupied by the cicatrix, so that none of this rested on the ground; movement at the ankle was very free, probably in a measure to compensate for the loss of the tarsal joints, and he declared it was as sound and as strong as it had been before the accident.

W. R——, aged nineteen years, was admitted on March 1st suffering from a bullet wound on the outer side of the right arm, just above the middle. A chamber of a revolver, which some friend was handling, had gone off accidentally, and the bullet had gone through his coat and shirt. A probe passed into the opening could be felt in the inner side, close to the brachial artery, immediately under the skin; but though he was perfectly clear about the exact position of his arm at the moment (his elbow was resting on a high desk), and though the accident had only happened an hour or two before, no trace of the bullet could be felt. It had gone apparently beneath the biceps in front of the bone, and most probably had been gradually pushed further and further into the cellular tissue of the arm by the repeated changes in shape and consistence of the muscles as they contracted. The artery itself seemed uninjured, though the bullet must have gone exceedingly close to it. The nerves had escaped in all probability, as there was no pain or abnormal sensation felt in any of his fingers, and accordingly no serious attempt was made to remove it. A counter opening was made through the skin on the inner side in case any portion of his clothes had been carried in, and the arm was placed in a sling. There was a slight amount of suppuration, but the wound was practically healed at the end of a week.

F. S——, twenty-three years of age, was admitted on March 18th with a bullet wound of the gluteal region. Some time before he had been shot with a revolver by accident in this region, and the bullet had never been extracted. Now he came desirous of having something done, as he asserted that after sitting down for some time he could distinctly feel it. There was the scar of the wound about two inches below and to the inner side of the trochanter; and it could be made out that the bullet had gone upwards and forwards with the substance of the glutæi muscles; but as nothing whatever could be felt on deep pressure, either over the bullet track or over the spot of which he complained, and as the latter was some distance from the aperture of entry, nothing could be done. In all probability the bullet had travelled some considerable distance before becoming encysted.

A. C—— and L. C——, mother and daughter, were admitted on June 30th, with gunshot wounds of the head and face. The former was much the more serious case; a revolver had been discharged close to her face, and the bullet had gone through the upper lip a little to the left of the middle line, through the alveolar border of the upper jaw into the substance of the tongue, beyond which it was impossible to trace it, though a certain amount of indistinct swelling could be made out between the angle of the jaw and the hyoid bone on the right side of the neck. There was at first a considerable degree of shock and much apprehension; but this passed off in the course of the afternoon, and beyond the natural difficulty in speaking and swallowing there did not seem any reason for grave alarm. None of the large vessels about the root of the tongue had been injured; there was no bleeding at the time of admission, though it was said to have been rather free at first; respiration was not embarrassed; there was no stridor; the voice itself was quite clear, though the effort was very painful; and there did not seem any reason for immediate interference. The next morning, however, the swelling by the side of the neck had greatly increased in size; all the parts about the floor of the mouth, and even the soft palate, were becoming œdematous; there was severe pain at the back of the neck and considerable difficulty in breathing; the patient was getting anxious and restless, and the temperature had risen to 101° F. It was accordingly determined to examine the part under an anæsthetic, and, if possible, extract the bullet and drain the wound thoroughly. Chloroform was administered on lint, but at the fourth or fifth inhalation the patient was suddenly seized with violent convulsions; the back became arched into the position of opisthotonos; the jaws were clenched, and the wrists and elbows curled inwards as much as possible. Respiration at once became embarrassed; the jaws were forced apart, and the tongue pulled forward, without avail; the trachea was opened immediately through the first and second rings, and as the convulsion was relaxing artificial respiration was commenced;

Digitized by Google

the pulse could still be felt beating, but except one or two convulsive gasps there was no sign of returning animation. Post mortem it was found that the bullet had entered the dorsum of the tongue, about its middle, passed through the tissues at its base, and was resting on the transverse process of the fourth cervical vertebra, between the carotid artery and pneumogastric nerve, neither of which, however, appeared to be injured. The tissues along its track were swollen and œdematous, but the œdema did not appear to have involved the larynx to any considerable degree. There can be no doubt, in spite of the unusual character of the symptoms, that the immediate cause of death was the anæsthetic, but it is not unlikely that the previous condition of the patient and the state of the tissues about the upper part of the respiratory passages were material factors.

L. C——, aged twenty-two, daughter of the previous patient, had been shot at the same time. She was holding her hand up to her face at the moment the revolver was discharged, and one of the fingers was almost blown away. The bullet then entered the right side of the face immediately above the zygoma, and passed transversely across almost to the opposite cheek. The aperture of entry was blackened all round by the powder. A probe inserted into it passed for nearly six inches slightly downwards across the nasal fossæ, apparently into the substance of the opposite superior maxilla. It could not be felt underneath the skin, though there was a good deal of tenderness, and an indefinite degree of swelling over its extremity. The exact situation of the bullet could not be made out. Previously to admission she had lost a good deal of blood, both by the mouth and nostrils, but evidently no large vessel was injured. Her speech was rather thick and nasal; there was some difficulty in swallowing, and naturally mastication was exceedingly painful. The temperature on the day after the accident rose to 100° F., but fell to normal the same night, and never rose again. The bullet was never found, and the wound closed completely in the course of a fortnight without more than a trace of suppuration.

These cases were admitted under my care at the London Hospital from Jan. 1st, 1886, to Jan. 1st, 1887. One man died before he could be brought. Some of them are of interest from the peculiar nature of the injuries received; one in particular, as the bullet is in all probability still lodged in his brain; and another from the fact that though the whole charge of shot had gone completely through his foot, leaving an opening into which three fingers could have been passed, he recovered without the least fever, without any inflammation, and so perfectly that at the end of six months he could walk four or five miles without fatigue or inconvenience. A point worth noticing is the extraordinary frequency with which accidents of this kind occur, mainly owing to the pernicious custom of carrying revolvers. Few people probably are aware of the extent to which this prevails, especially among boys and those a few years older. The only consolation is that in a large proportion of the cases, owing to the character of the weapons, they are nearly as likely to shoot themselves as anybody else, and that apparently, if no vital part is struck, the bullets themselves, when lodged in the body, give rise to little or no trouble. The immediate shock, owing probably to the smallness of the size of the projectile and its conical shape, is very slight, and the wound heals rapidly.

ON A CASE OF CHRONIC RHEUMATISM.

BY CHARLES DAY, M.R.C.S., &c.

"CURE of a case of rheumatism of thirty-six years' standing" sounds so like a sensational heading of an account of the marvellous effects of some patent medicine that one almost hesitates to enter on a subject having such a basis. Nevertheless it is a fact, and as facts are—as we too generally find chronic rheumatism to be—"stubborn things," and as the annals of medicine record many remarkable exceptions to the general rule, I will detail a brief history of the case, adding a few remarks suggested by the result.

In July, 1883, I was requested to visit Miss R——. I found the patient, a maiden lady, aged sixty, suffering from much anxiety in consequence of having discovered that the right nipple was deeply retracted, so as to be quite level with the surface. I also heard that she had been a great sufferer from rheumatism for many years; and as it is to this disease rather than to the cancer that my communication relates, I will merely observe how insidiously and painlessly this complaint—cancer—sometimes makes its way, and also the somewhat remarkable circumstance that women, whose attention would naturally be directed to the breasts during the daily ablutions, and quickly notice any change in the appearance of the nipples, do not always observe a gradual process of retrocession. I have met with several cases, as in the present instance, and no doubt the same circumstance has fallen under the notice of other medical men, that there has been complete ignorance of any abnormal change in the condition of parts until their attention has been called to the sudden entire retraction of the nipple, generally described as having occurred in the night. On making further general inquiries, I found, as I have stated, that, as well as the cancer, I had before me a case of very long-standing rheumatism, which all treatment had failed to relieve. The lady is 5 ft. 4 in. in height; body well nourished; fair complexion; cheerful disposition. The family history revealed no gout or rheumatism, but a sister died of cancer.

The following account was given of the commencement of her illness and condition up to the time of coming under treatment. During very hot summer weather, thirty-three years previously to the time of my attendance, she sat between the open door and window while in a state of perspiration, "the draught being so delightful." A very natural result followed—viz., a very severe attack of acute rheumatism, from which she was three months in recovering. I could not hear that there was any cardiac complication at the time, but the heart sounds are healthy now. The pain and swelling of the joints were considerable, which condition of parts never entirely subsided. Another less violent but still sharp attack was experienced eight years afterwards, and again four and two years before I saw her. The last was more confined to the lumbar region, and was very severe. During the whole of the long period named she cannot remember having been entirely free from pain. Going up and down stairs (especially the former) was attended with pain and difficulty, and could not be accomplished without the help of the baluster, the progress being very slow, step by step. Out-door exercise, except for a short distance leaning on an attendant, was impracticable. Any attempt to walk alone immediately produced giddiness and a staggering gait, and if not supported she would fall to the ground. A sharp pain was frequently experienced at the top of the sternum, which increased on any attempt to swallow, causing a choking sensation; consequently all fluids were taken by sips. The night's sleep was very interrupted.

As the treatment continued over some considerable time, it would be inconvenient here to give a minute account of it. For the present purpose it will suffice to give a general statement of the medicines administered and the gradual progress up to recovery. Taking, then, a general view of the case, the invasion and long-continued possession of the system by the rheumatic virus and the mammary glandular disturbance, one was led naturally to select medicines calculated to have a specific action on the parts, and a depurative action on the blood through the excretory functions. I therefore commenced with iodide and bromide of potassium, five-grain doses of each in compound decoction of sarsaparilla and decoction of buchu and broom. And having proved, at least to my satisfaction, that the influence attributed in past time to conium over chronic rheumatism and glandular enlargement is real, I administered three grains of the extract every night and morning. This treatment was continued for twelve months, with only occasional intermission of the potassium and conium, substituting infusion of simarouba with aromatic spirits of ammonia. At the end of this time the swelling of the joints had subsided, and the patient was relieved of the pain which hitherto had made its presence felt so continually. She could also move about the house without the assistance previously necessary, but still not freely; neither could she take out-door exercise without assistance; the giddiness also continuing. At this time the iodide of potassium was discontinued; the bromide and conium were omitted every other week for three months, every third week for the next three months, finishing the year with simarouba. At the end of this time she had regained fair powers of locomotion, could move about the house freely, going up and down stairs without help, and could take a short walk without support, but did

Digitized by Google

not feel confident without a companion. Six months after this there was no vestige of rheumatism, joints natural, pain quite gone. Even that in the chest, which had interfered with her swallowing fluids except by small sips, was no longer experienced, the power of swallowing being natural. Sleep was continuous from soon after retiring to rest until the time for rising, a contrast to the pain and restlessness of former times. The general health is now excellent. To use her own expression, she "scarcely knows herself," for whereas during the whole thirty odd years she does not remember having been free from pain, she is now entirely free from it; and whereas she had been unable to move about the house or go out without assistance, she can now go out by herself, and has walked four miles without a rest. Indeed, it has afforded some amusement to hear her expressions of delight, and the description of the tests which she has applied to satisfy herself that the improvement was real. On a recent occasion she was in the park, when, looking round to see that no curious eyes were watching her, she said to a relative who was with her—"Don't laugh, I am going to run," which she did with great satisfaction to herself.

With regard to the treatment and its success. Although there is no claim of novelty to be applied to the remedies used, that they were effectual in promoting the desired end is manifested by the result. There is a wide gulf between disbelief of, and exaggerated confidence in, medicine—the one objecting to any *propter hoc* reasoning, the other accepting without question the empirical dogma. The long period during which the iodide, bromide, and conium were continued without producing any constitutional disturbance is not a little remarkable. Only twice had the iodide to be discontinued in consequence of the characteristic catarrhal symptoms. In like manner the conium was discontinued for a short time on three occasions, not from any evidence of toxic action, but from a feeling that it might be prudent to do so. The system had become so tolerant of the medicines, or, as one might say, the disease had so "consumed" them, that they might have been continued for a much longer period. It may be inquired, How do these medicines act?—which almost necessitates another question, What is rheumatism?—too wide a matter to discuss here. Suffice it that we observe the same divergence of opinion as elsewhere. We have certain forms of words to express the difference between health and what we call disease. We analyse the blood and secretions to discover the *fons et origo mali* without producing uniformity of opinion. Hence in the treatment we find remedies of opposite characters employed for the cure of the same malady. Thus in the acute stage of rheumatism one considers the alkaline treatment to neutralise the excess of acidity in the system the only natural one, while another administers large doses of lemon juice. One will attack cholera with purgatives, another with astringents and opiates; one with cold water, another with hot water; and so on. From time to time the field of argument changes. That which was pretty firmly established in one generation is rejected by the following. Whatever may be the nature of the physiological changes effected in this complaint, rheumatism, it appears from the symptoms in its acute development to be rightly classed both under febris and neurosis. Hence in that stage remedies are sought for amongst those which reduce temperature and allay pain, and the chemical theory of neutralising the acid secretions is rational in theory and useful in practice. But when we come to a chronic condition less susceptible of a satisfactory explanation we are reduced to a more empirical system of treatment, the *rationale* of which we are somewhat at a loss to understand. The iodides and bromides are present to the mind, and have been used with temporary benefit or with no effect. Conium has been employed with marked benefit in chronic rheumatism and in syphilitic periosteal inflammation. With these were joined buchu, broom, and sarsaparilla, with the object of assisting to eliminate from the system the *materies morbi*. Now, I attribute the success of the treatment to its regular and long-continued administration. It is very seldom one meets with a patient so willing and anxious to assist by strict adherence to directions, especially for so long a time, and the unusual tolerance of the medicines gave full opportunity for the trial. One other thought suggests itself to me. In a contribution on fibroid disease, which was published in THE LANCET, I was led to theorise on the relative connexion between those diseases of heredity, cancer and gout, referring to cases where one had been replaced by the other, relating the case of a family which, having for generations suffered from gout, suddenly developed cancer, the former disease disappearing and the latter carrying off the members of two generations. If there be any ground for the idea of substitution, it may be just possible in this instance that, as cancer was developing, the rheumatism so closely allied to the gouty diathesis may have weakened its hold and rendered it more ready to yield to the remedies employed. Be that as it may, I think, taking into consideration the many years during which this poor woman was bound by her infirmity, and despite the medical care she had received at different times, the favourable result now obtained must, without any forced argument, be accepted as the direct result of the action of the remedies used; and, as they are not novel, there is evidence to show that their long and continuous exhibition is necessary to produce such a result.

St. Mark's-square, E.

TWO CASES OF

DISEASE OF SACRO-ILIAC SYNCHONDROSIS.

BY F. J. GANT, F.R.C.S. ENG.

CASE 1.—C. M——, aged thirty-six, married, was admitted into the Royal Free Hospital on March 2nd, 1887. The patient had always been healthy until Christmas, 1886, when he first noticed a swelling over the sacrum to the left of the middle line. He had fallen from a ladder eighteen months previously. When admitted this swelling was found to be soft and fluctuating—evidently an abscess, painful only on deep pressure. On standing, the man complained of a sensation as though the left half of the pelvis were giving way, and of pain running down towards the hip. No wriggle in walking. Viewed posteriorly, the left limb appeared elongated, but there was no real alteration in length when measured between the anterior superior spine and inner malleolus, the apparent lengthening being really due to the patient habitually standing on the right leg, and thus producing drooping of the opposite limb. There was some abduction and eversion of the limb, with slight forward projection of the foot. The anterior superior iliac spine was more prominent than on the other side, and on a somewhat lower level. The above-mentioned swelling had enlarged, so as to occupy the adjoining portion of the gluteal region. On April 19th I made an incision over the swelling, and pus escaped. At one point a small aperture could be felt, through which a probe passed into the sacro-iliac articulation. This was enlarged, and the articulation gouged out until the surface appeared healthy. The abscess cavity was scraped with a Volkmann's spoon, and washed out with 1 in 40 carbolic solution. A drainage tube having been introduced, the wound was dressed with dry carbolic gauze and salicylic wool, and closed with mackintosh cloth and retained with elastic bandage. The wound rapidly healed, and the temperature reached normal in two days. The dressings having been reapplied as occasion required, the patient was discharged on May 22nd. He could then walk and stand without inconvenience.

CASE 2.—E. G——, a young woman, aged nineteen, was admitted on June 29th, 1887. She was by occupation a box-maker, which for the last three years had entailed much standing in her work. Nine months ago she first noticed a small lump nearly over the left sacro-iliac articulation. This slowly increased in size from a hazel-nut to about the size of an orange. She had received no injury. In standing or walking, she experienced a sensation, as she herself expressed, of "falling asunder behind." Pressure on the iliac bone outwards by the finger caused severe pain in the articulation. The movements of the left hip joint were free and unattended by pain. The appearance and position of the limb were precisely similar to those of the former case, there being apparent lengthening with abduction and eversion. The anterior superior iliac spine projected conspicuously forwards. On July 12th the abscess was opened, from two to three ounces of pus evacuated, and the synchondrosis scraped, as in the last case, together with the pyogenic membrane. The cavity was syringed out with carbolic solution (1 in 40), drainage tubes introduced, and antiseptic dressings applied. The after course of the case was uninterrupted by any unfavourable symptom, and now (July 19th) the wound is quite healthy and healing up.

Remarks.—The above cases seem worthy of being recorded, if only on account of the rarity of the disease of which they are

Digitized by Google

examples. This is only the fourth case that has come under my notice during thirty-four years at the hospital. The diagnosis would lie between this disease and that of the hip joint. In the early stage at which both of these cases presented themselves, the sacro-iliac disease bore a striking resemblance to the first stage of "morbus coxæ," with regard to the apparent lengthening and attitude of the limb; but the marked prominence of the iliac spine in front is distinctive. Equally characteristic is the sensation of yielding in the articulation in the act of standing or walking, with sometimes a wriggling movement in progression. These characters taken together, with the absence of any signs or symptoms referable to the hip joint, are diagnostic of sacro-iliac disease.

A SERIES OF CASES OF INJURIES FROM EXPLOSIVES.

BY W. LOUDON STRAIN, M.B.

SURGEON TO ST. JOHN DEL REY MINING COMPANY; LATE HOUSE SURGEON, WESTERN INFIRMARY, GLASGOW.

DURING the last three years I have had to deal with a number of surgical injuries produced by various explosives, and I think them of sufficient interest to warrant their publication, with the short remarks I have to make on each case.

CASE 1.—This case I had to deal with while resident in the Western Infirmary. A strong working man on his way to work picked up a piece of copper tubing and put it in his pocket, intending to make some use of it. On reaching home he proceeded with the help of a darning needle to clean it out, when it exploded in his hand. On admission, it was found that the thumb, fore and middle fingers had been so shattered that amputations had to be performed through the proximal phalanx of the thumb, the middle joint of the forefinger, and at the knuckle of the middle finger. The man did well. This case is interesting when compared with Case 3. The explosive—fulminate of mercury—was the same in both cases, and the mode of production and damage sustained were almost identical.

CASE 2.—J——, a very old negro, certainly over eighty years of age, was brought to Morro Velho Hospital on Feb. 16th, 1886, terribly injured by the exploding of a quantity of dynamite and percussion caps, with which he was working. The old man's duties were to attach the cap and fuse to the dynamite cartridge. How the accident occurred will never be known. It is estimated that about 5 lb. of dynamite and about one hundred caps, with fulminate of mercury, exploded at the old man's feet. On admission he was not unconscious, and complained loudly of pain on any attempt to move him. His left foot, with the lower half of the leg bones, was shattered; the right leg bones were fractured in several places, and almost completely stripped of the soft parts. Beyond scorching of the skin and singeing of his wool, no damage was done to the head, trunk, or upper extremities, all the force of the explosion being exerted on his legs. The poor old fellow survived the removal of his shattered limbs about twelve hours.

This case illustrates how curiously dynamite acts. An inspection of the place where he was working showed a hole about a foot deep and two feet in diameter blown in the ground. The house came down about him, and a gable close by was blown in. The wonder is how he was not blown to atoms. The dynamite with which he was working was on the ground, and he sat on a little bench.

CASE 3.—On Saturday, April 4th, 1886, a Chinaman stole a cap, intending to use the tubing as a ferrule for a stick. Finding it obstructed, he proceeded to clear it out, when it exploded, shattering the thumb, fore and middle fingers of the left hand. Being almost identical with the injuries in Case 1, the amputations were also identical. At the end of a week the stumps were dressed, and looked well. Four days afterwards pain was complained of, and on removing the dressings pus was found lodging in small quantity in the sheath of the extensor tendon of the middle finger. This was freely incised, and relief followed, but three days afterwards tetanus appeared, and in exactly three weeks from the date of the injury he died asphyxiated.

What caused the tetanus? Had the faulty drainage—the pus lodging as it did in a tendon sheath—anything to do with it? He suffered from chronic tubular nephritis, with aortic regurgitation and dropsy. Had this anything to do with it? The only other Chinaman in the hospital at the time was a man suffering from anæsthetic leprosy, with ulcers. The two were continually together. I merely mention these three things, as I think it not improbable that one or other had to do with the origin of the tetanus. Calabar bean was given in large doses, and continuously, but without benefit. He smoked opium largely.

CASE 4.—In this case I will briefly narrate the injuries sustained by several persons in an explosion which occurred in a mine on April 9th, 1886. After blasting out masses of rock with dynamite the larger pieces are broken up with sledges to a convenient size for conveyance to the surface. On the above date a man was thus engaged, but on striking a mass of rock an explosion occurred, shattering the mass and sending pieces in all directions. Practical miners are at a loss to account for these explosions, which occur at rare intervals; but it is thought that it is due to nitro-glycerine which has exuded from the dynamite during the blasting and remained at the bottom of the "hole" unexploded, and that the sledge coming down on this causes the explosion.[1] This is a matter of importance for the consideration of dynamite makers. By this explosion five persons sustained serious injuries. J——, an Italian, sustained a compound comminuted fracture of the tibia just above the ankle, total destruction of the right eye, and numerous cuts and scratches. Ten small fragments of bone were removed from the seat of fracture, and three days afterwards extirpation of the eye had to be performed on account of pain. He made an excellent recovery. C——, a Brazilian, was using the sledge. He escaped with a simple fracture of the tibia below the knee. T——, a black man, had a severe laceration of his right arm, and across the left side of his throat there was a deep, clean cut, which bared the side of the larynx and also the carotid, which most wonderfully escaped injury. He suffered from profound shock, from which he did not recover for twelve hours. After this, recovery was uninterrupted. A——, a black man, had a deep punctured wound in front of his left shoulder. A small artery was wounded, and bled so profusely that I had to cut down and tie it. He suffered a good deal from loss of blood. L——, a black man, was cut across the right eyeball, which was completely destroyed. One curious incident occurred. A man was actually standing on the stone when it exploded. He was thrown for a considerable distance up an inclined surface, but escaped uninjured. All these men were employed close to the place of explosion, besides many others who escaped uninjured.

CASE 5.—Senhor J. F. P——, a Brazilian, aged about sixty, was terribly injured by the exploding of a dynamite cartridge in his hand. It occurred in the following manner. On a certain day after Easter the terrible fate of Judas the Betrayer is typified or commemorated by the exploding of bombs, firing off rockets, &c. On this particular occasion dynamite cartridges were used. A short piece of fuse was attached to the cartridge, which was held in the hand until the fuse was seen to have caught fire; then the intention was to throw it away as far as possible for it to explode. The sun shining brightly at the time obscured the sparks flying from the fuse, and thinking it had not caught fire the man held it in his hand until the explosion occurred. I may incidentally remark that the use of dynamite and other dangerous explosives at their religious and other festivals prevails to an alarming extent amongst the Brazilians, and is winked at by the authorities. However, this case has had a very salutary effect in diminishing the nuisance. I was on the spot in about a quarter of an hour, and found the man on the floor in an unconscious state. His right hand was blown off just above the wrist, and his right eyeball burst; a day or so after I also found both tympanic membranes burst. The amputation of the hand was completed, and a great gash in the palm of the left hand was dressed. The shock was very severe, and required free stimulation for twenty-four hours. On the third day the pain in the destroyed eye was so great that I had to extirpate it. The man's recovery was very slow. Sloughing of the palmar flap occurred and much retarded healing; but after two months he was able to be on horseback again—"a sadder but a wiser man."

This case is of interest in showing the very localised action of the dynamite. The bursting of the eye and

[1] Experienced miners here say that in mines where dynamite is largely used, exuded and unexploded nitro-glycerine is frequently met with, and is a recognised danger in using dynamite for blasting.

Digitized by Google

tympanic membranes was induced by the concussion, and beyond scorching his chest and face no other damage was sustained.

Whilst writing the above another explosion has occurred similar to Case 4, but happily without doing serious injury.

I am fully aware that no special point of surgery is illustrated in the narration of these cases, and it is not with that intention that I record them. They are interesting and also instructive, in so far as they show a necessity for the greatest care in the manufacturing and using of such dangerous articles. I might say more on this point, but a medical journal is hardly a suitable medium.

Morro Velho, Brazil.

CASE OF VAGINAL HYSTERECTOMY FOR MALIGNANT DISEASE.

BY FERDINAND A. PURCELL, M.D.,
SURGEON TO THE CANCER HOSPITAL.

THE case of extirpation of the uterus and its appendages per vaginam which I have to report makes my fourth successful case. A record of the three previous cases appears in a paper by me, and is published in the *British Gynæcological Journal* (May, 1887, Part ix., p. 60), and was read before the Society on March 9th of this year. I intend to give a full report of this case to show that I have not, with my additional experience, departed from the plan of operation followed in my first three cases.[1]

We may take it for granted that kolpo-hysterectomy is only justifiable when the body of the uterus is cancerous, or when the disease commences near the os internum; and unjustifiable for cancer of the cervix alone, or when the walls of the vagina have been encroached upon, for in the latter condition the surrounding cellular tissue has already been infiltrated, and recurrence after operation will undoubtedly take place in a very short space of time.

Operators are still divided as to the details of the operation: as to whether the peritoneum should be entered in the anterior fornix or the posterior fornix; whether the fundus is to be brought down through the anterior wound or the posterior one; or not to make the uterus perform a somersault at all, so as to avoid all risk of soiling the peritoneum with the discharges from the diseased os and neck; or whether it is not advisable to remove the diseased cervix as a preliminary operation by amputation or with the curette; whether the broad ligaments should be ligated *en masse*, or in segments, or to rely on pressure forceps to be left *in situ*; whether the ovaries ought to be removed; whether the vaginal walls and peritoneal edges should be brought together with suture, or leave the vaginal wound unclosed; and whether a drain is to be used.

Mrs. Eliza K——, aged forty-six, was admitted into the Cancer Hospital on June 17th, 1887, being a patient sent to me from Birmingham by Dr. John W. Taylor, who had curetted and cauterised the os and cervix about three months previously at the Birmingham Hospital for Women, and where she was at the time examined by Mr. Lawson Tait. The patient is a fairly well-nourished woman, the mother of one child aged twenty-four years, and had always enjoyed good health until about twelve months ago, when she had vomiting of blood and violent pains across the pit of the stomach and back. Three months subsequently (Sept. 1886) a vaginal discharge came on, and pain, with difficulty in micturating, necessitated treatment under the care of Dr. John W. Taylor, and in January he performed an operation on the ureters. Some six weeks later malignant disease of the os and cervix was discovered; for this she was examined, in conjunction with Dr. Taylor, by Mr. Lawson Tait, and had the os and cervix curetted and cauterised by Dr. Taylor. Recurrence of the disease showed itself about three weeks ago, for which Dr. Taylor advised kolpo-hysterectomy, and kindly sent her to me. The disease now occupies the stump and neck as far up, if not beyond, the os internum; walls of the vagina are sound. On examining with the two fingers in the rectum and the other hand over the pubes, the body is found larger than normal, more particularly its left half; the organ is freely movable, and the broad ligaments appear healthy; no enlarged glands are to be felt. She has passed the menopause. There is no family history of cancer or of phthisis to be made out. Father died at seventy-nine; mother died at seventy-two, having had thirteen children. After a consultation with my colleagues, and having decided that removal of the uterus was justifiable, fully explaining the nature and risks of the operation to the patient, as also to her husband, and which they had had previously explained to them by Dr. Taylor, consent was given and the best wished for.

On June 23rd I proceeded to operate, assisted by my colleagues, Dr. Snow and Mr. Jessett. Dr. John W. Taylor came up from Birmingham and was present, as also Mr. Henry Reeves, and other visitors. The patient was placed in the lithotomy position, the bladder emptied, and vagina and parts douched with carbolised water; a duck-bill speculum in the posterior fourchette, aided by the fingers of my assistants, brought the parts well into view. Steadying the uterus by fixing a vulsellum in the cervix, the mucous membrane was incised all round, the anterior and posterior flaps reflected upwards, the bladder kept out of the way, and a segment pinched up laterally (first one side then the other), and a ligature passed through it with an aneurysm needle, so as to include the lower uterine vessels, was tied, and divided away. The peritoneum was entered both anteriorly and posteriorly, and the apertures enlarged by tearing; the two fingers of the right hand were passed up through the anterior opening and over the fundus, and then over the right broad ligament, which it was made to encircle. Now a silk thread was passed by means of a long well-curved aneurysm needle on the finger, until it encircled the broad ligament and insinuated down posteriorly; the thread was hooked out of the eye and the needle withdrawn; the broad ligament was gently drawn down and examined for absence of ureter. Feeling satisfied of its not being present, the ligature was tied. Tying the broad ligament *en masse*, close up to the ligature on its uterine side, I applied two pressure forceps as a guard, and, cutting the thread short, divided the parts away from the uterus with scissors. The pedicle receded together with the forceps; the uterus sidled down, presenting its right cornu; the left-hand fingers now were passed in front and above the left broad ligament, followed by a silk thread, which was passed through the substance double. Having examined for absence of ureter and not observed, it was tied double and again encircled, clamped with pressure forceps and divided. The Fallopian tube was not included, and on bringing the uterus down, which was now free, the left ovary came down along with it, and on gently drawing, the Fallopian tube followed, when all was withdrawn; the Fallopian tube on the right side had been included in the pedicle, but now the right ovary was felt for and brought down, its attachment tied and severed, and it was got away. Parts around and within were douched, cleaned, and dried; there was no oozing of blood, and little blood was lost. The pressure forceps were all carefully taken off; no attempt at closing the vaginal or peritoneal wound was made. Bladder and bowel and surrounding parts were finally examined, a glass drain, with its end rounded, but perforated, was inserted; this and the vulva was covered up with a large pad of salicylic wool and fixed by a T bandage; patient was removed to her bed in the general ward. The operation from first to last occupied one hour and twenty minutes.

In the evening, after operation, the pad and draw-sheet were found saturated with coloured water. Four ounces of urine were drawn off, and it was ordered to be drawn off by catheter when necessary. Temperature ranged between 96·8° and 97·4° F. The patient partook of ice only.

June 24th.—Patient passed a comfortable night; had no sickness. Five ounces of urine drawn off. Salicylic wool pad dry; renewed. Iodoform dusted about and up the drainage tube; tube not interfered with. Pulse 74, intermittent; temperature (twenty-four hours) ranged between 98·2° and 100·2°.

25th.—Slept at stretches of an hour; comfortable; no sickness. Was given six ounces of barley water during the night, and one drachm of essence of beef given twice; pad dry. Urine free. Temperature (twenty-four hours) ranged between 100° and 99·4°.

26th.—Very comfortable night; slept two hours at a time. Urine drawn off. Pulse feeble and intermittent. Pad dry. The drain taken out for the first time; only a small piece of shred found clung in a couple of the holes; its inner surface is coated with iodoform; no smell; cleaned and replaced as before. Diet increased—fish, the essence of beef

[1] For Art. see THE LANCET, Jan. 31st, 1885, p. 200.

Digitized by Google

more frequently, barley water, and arrowroot. The temperature during the forenoon was 99·6°; afternoon to midnight it ranged from 100° to 101·4°.

27th.—Took nourishment well. At 5 A.M. complained of sickness and pain in left iliac. Urine drawn off. Abdomen is tympanitic. Passed some flatus, but with difficulty. Slight discharge found in the glass drain. Applied a turpentine fomentation, which relieved her. The wool pads were more soiled later on. Temperature for twenty-hours ranged from 99·4° to 101·8°.

28th.—Slight pain in left iliac; urine drawn off; pad not much soiled; tube contains pus; taken out and cleaned; was reinserted, and then iodine water was injected through it, bringing away some purulent discharge enough to colour the water. Temperature 99 6° to 101 8°.

29th.—Complains of a throbbing pain in urethra; pad slightly soiled. Temperature 99·6° to 102·4°. To have a turpentine enema; iodine water douches to be continued twice a day.

30th.—Temperature was high all night; rose to 101·8°, and in the afternoon from 101·8° to 102 4°; enema acted slightly; pad but little soiled. To have a teaspoon of oil.

July 1st.—Slept well and taken nourishment. The tube is half full of pus; the syringing with iodine water has been done night and morning regularly. Temperature 101·8°, 99 2°, and 100 6°. Bowels acted well.

2nd.—Pulse 66, regular; eats well; discharge of pus continues. Temperature 100 4° to 98·4°.

10th.—Discharge lessened every day. The tube is now removed, and she is permitted to pass urine of herself, and allowed up on the couch. From this she became convalescent and began to walk about. Examined the vagina; found that the two fingers passed up to their full length; the vault is broad, and not at all contracted; the broad ligament pedicles distinctly to be felt. Returns home to Birmingham.

Manchester-square, W.

ON A

METHOD OF DETECTING AND REMOVING NEEDLES EMBEDDED IN THE TISSUES.

BY H. LITTLEWOOD, F.R.C.S. ENG.,
RESIDENT SURGICAL OFFICER TO THE LEEDS GENERAL INFIRMARY.

I BELIEVE the general advice given by surgeons when a needle becomes embedded in the tissues, if it cannot be felt, is "to let it alone," with the hope that it will either work its way out or become embedded where it will give rise to no trouble; the reason being that the task of removal under these conditions is always very difficult and often impossible—almost like looking for the proverbial needle in the haystack. Having had several such cases, where I could not be actually sure of the presence of the needle, I have gone on the plan of "letting alone"; in two or three cases the patients have come to me several weeks after, bringing the needle, which had worked its way out, they having in the meantime undergone several weeks of pain and mental anxiety. These cases led me to try if it were not possible first to detect the presence of, and then remove, the needle. Since then I have adopted the following plan with considerable success.

1. The part supposed to contain the needle is thoroughly rubbed over with an electro-magnet, so as to magnetise the metal if present. 2. A delicately balanced magnetic needle is held over the part. If the needle is present, its position can be ascertained by the attraction or repulsion of the poles of the magnetic needle. 3. Having ascertained the presence of a needle (e.g., in the hand), the part is rendered bloodless, and a grain or more of cocaine injected hypodermically. 4. An incision is made over the ascertained position of the needle. 5. The electro-magnet is then inserted into the wound, and with it the needle is felt for. Sometimes it will be found and removed quite easily, at others great difficulty will be experienced, taking as long as one-half or three-quarters of an hour. This may be due to the fact that its position has not been accurately ascertained; it may be lying across the incision, or it may be so firmly embedded in the tissues that the electro-magnet is not able to withdraw it. If this occurs the incision must be enlarged, and the edges held apart with some non-magnetic retractors; using the electro-magnet as a guide, the needle may be seen and removed with forceps. If the needle is firmly fixed, the following plan has been adopted: by placing the positive pole of a galvanic battery on the surface of the body and the negative pole in direct contact with the needle, this becomes loosened by electrolysis and can then be easily removed by the electro-magnet. This latter method has been found useful in two cases for the removal of sewing machine needles that had transfixed the end of the finger, and were so firmly fixed as not to be removable by forceps. The electrolytic action loosened the needles so that they could be removed quite easily.

Mr. Marshall, in his lectures on Surgery at University College, used to tell us that needles &c. could be detected in the tissues by the method described above. I had not seen it practically tested. After having removed two or three needles by the method described above, I referred to Neale's Digest to see what had been written on the subject. I find the following references which I think will be of interest:—In the *Medical Times and Gazette* (vol. i., 1857, p. 298) is a paper by Dr. Bence Jones, entitled "On a ready method of determining the presence, position, depth and length of a Needle broken into the Foot." In the same journal (vol. ii., 1876, page 531) is a paper by Sir Benjamin Brodie, in which the presence of a needle in the leg of his own son was demonstrated at the Royal Institution by means of the electro-magnet. It was not then removed, but allowed to remain in some time, until it worked its way to the skin on the opposite side of the leg, and then removed. Both these papers refer only to the detection of the needle. In THE LANCET (vol. ii. 1876, p. 700) is a communication by an army surgeon named Thompson describing a case in which he made an incision over the site of a piece of metal embedded, and then bandaged an ordinary magnet over the part for twenty-four hours, with the satisfaction of finding the metal attached to the magnet at the end of that time.

I have now removed six needles from the hand and a piece of steel embedded in the foot. In none of the cases could I feel the piece of metal or be sure of its presence without the aid of the method above described. As it requires some expensive apparatus, and sometimes takes a long time, I am afraid this method will not become general; but it is well worth the time and trouble spent if in the end one is successful; as patients really suffer a good deal of pain and anxiety if these foreign bodies are allowed to remain embedded in the tissues.

ON THE PATHOLOGY OF HEMIPLEGIA.

BY FRANCIS W. CLARK, L.R.C.P., M.R.C.S.,
ASSISTANT MEDICAL OFFICER TO THE CROYDON INFIRMARY.

As the pathology of certain cases of hemiplegia is still somewhat obscure, I venture to give a brief *résumé* of some thirteen cases of the disease which have come under my care during the past year, with a view to suggesting that some of these depend, in all probability, upon a chronic pachymeningitis of the vault due either to alcoholism or more rarely to rheumatism.

Of the thirteen cases three were due to massive hæmorrhages into the brain, as verified by post-mortem examination; and hence these cases need not detain us at all.

Of the remaining ten cases, in two only were there any evidences of morbus cordis. The first of these—George K——, aged forty-five—had an attack of right hemiplegia, with *left* facial palsy, from which he recovered to a great extent in the course of a few weeks. Four months later, however, he succumbed to the effects of the morbus cordis, but, unfortunately, no necropsy was granted. The crossed paralysis in this case is suggestive of the lodgment of a small embolus in the pons Varolii.

The other case associated with morbus cordis was that of Jesse Y——, aged sixty-eight, who had an attack of left hemiplegia six years ago, from which he recovered in a short time; a second attack, on the same side, four years ago, with recovery; and he is now convalescent from a third attack, also on the left side, but this time associated with difficulty of articulation. As there is in this case also a history of alcoholism, I shall refer to it again under that head.

In one case only was there a history or any evidences of syphilis—namely, that of a young man (J. P——) aged

Digitized by Google

thirty-six, who rapidly recovered from an attack of right hemiplegia under the influence of iodide of potassium.

In two cases the hemiplegia was associated with occasional epileptic attacks: one of these being a man (J. H——) aged forty-eight, who has had right hemiplegia for some years past; and the other, a woman (S. H——) aged fifty-seven, who had an attack of left hemiplegia, from which she recovered in the course of a few weeks, and in whom there was a strong history of alcoholism.

Of the remaining five cases, one had been bedridden for some months with chronic rheumatic arthritis, while in the other four there was a well-marked history of alcoholism.

Mary G——, aged seventy-one, of a marked rheumatic diathesis, was suddenly seized with paralysis and anæsthesia of the left arm; the left leg was cold and anæsthetic, but not paralysed. Four days later the paralysis had much improved, and it continued to improve slowly until her death, which occurred twenty-five days after the seizure. At the necropsy the dura mater of the vault was found thickened and adherent to the brain along the median fissure, but otherwise both brain and spinal cord appeared perfectly healthy. The heart was fatty, but otherwise normal, the lungs œdematous, and the kidneys normal.

The cases with a history of chronic alcoholism were as follows:—

George T——, aged forty, had a sudden attack of right hemiplegia, from which he recovered in the course of a few weeks.

Mary Ann W——, aged fifty-seven, had an attack of right hemiplegia eighteen months ago, from which she has been for some few months convalescent.

Robert C——, aged sixty, had an attack of right hemiplegia, with rapid recovery.

William W——, aged sixty-eight, had an attack of left hemiplegia with amnesia four months ago, from which he recovered in about a month. A second attack occurred a month ago, this time on the right side, and again associated with amnesia, from which he is now convalescent, the amnesia, however, remaining.

Also in the two cases mentioned above—namely, Jesse Y—— with associated heart disease, and Sarah H—— with occasional epileptic attacks—there was a well-marked history of chronic alcoholism.

In none of these cases was there any facial palsy. Hence it would, I think, appear that, in these seven latter cases at least, the transient nature of the paralysis, its alternation from side to side, as illustrated in the case of Wm. W——, its frequent recurrence, as specially illustrated in Jesse Y——, and again the results of the post-mortem examination of Mary G——, are all of them suggestive of some temporary pressure upon the cortex of the brain such as would be occasioned by a slight and transient kindling of the chronic inflammation of the dura mater of the vertex, so common in the later stages of chronic alcoholism, and to a less extent of chronic arthritic rheumatism.

CASE OF
CHRONIC HYPERTROPHIC CIRRHOSIS OF THE LIVER; WITH REMARKS.

BY ALEXANDER YULE, M.D., C.M. ABERD.

JOHN T——, aged sixty-three, a Sussex labourer, came under my observation in 1880 suffering from dyspeptic symptoms and difficulty of breathing. This would last for a few days, and his usually indifferent health followed. I examined his chest, and observed that at one time he had had empyema. There was a cicatrix under the left breast; the lower half of the left side had fallen in, and the lung shrunk. This occurred many years before I first saw him. The want of breathing capacity and feeble action of the heart I attributed to the changes in the chest. I examined the heart frequently, and failed to find a murmur. There was at first a little swelling of the feet and lower part of the legs. The size of the abdomen varied according to the action of the bowels and kidneys, but at all times was much distended with serum. The liver was enlarged in every direction, and the urine albuminous. In 1883 and 1884 increasing anæmia and dropsy supervened, associated with which were symptoms referable to kidney, liver, and lungs—viz, transient and recurrent jaundice, vomiting, &c. The disease proved fatal in July, 1885, from chronic hypertrophic cirrhosis and asthenia. The man had always been of sober habits, and there was nothing personal in his history differing from what is found amongst the labourers in these parts, such as exposure to the vicissitudes of weather.

From a physiological point of view these cases are interesting. In common parlance, it was a case of premature break-down, and beyond the remedial power of medicine. The patient inherited the seeds of the disease, to develop sooner or later, according to circumstances. He was unhealthy to begin with, the error being in the blood and in the organs that deal with nutriment. Be that as it may, the same constitutional dyscrasia that had caused a pleurisy to degenerate into an empyema, with, subsequently, much formation of fibroid tissue, when once the flood-gate of impure blood had been opened, led to degeneration in other parts. Why the liver should not have been the subject of gin-drinkers' cirrhosis I take to be in the difference of the originating causes: in the one case, alcohol being more of an irritant, inflammatory changes with thickening of the tissue resulting, and contraction; while in the other, added development of fibrous tissue, with increase of bulk. In the former case, one would expect the disease to be more rapid and painful on account of the greater activity of the poison. Lung affections and short breathing are common among those who have lived for some time in tropical climates, on their return to temperate parts. The liver is invariably affected. In these cases, not uncommonly, from sudden chill, a fatal congestion or bronchitis results, and there being possibly pre-existing fibroid affection of the lungs, may not that be a predisposing cause of the untoward event? The *rationale* would be evident. Blood dyscrasia, from the liver not performing its appropriate functions of depuration, alteration, or otherwise, and therefore the cellular structure of the lungs being supplied with unsuitable nutriment, perverted growth would ensue. Thus the vena porta brings blood to the liver, and it is altered there, and made fit for nourishment of tissues (altering venous blood in other systems before it is arterialised). However, when what is brought to the liver, or when the liver, from occult causes, in digestive or other parts (or in itself), causes a failure of proper nutrition, the tissues (lungs, kidneys, spleen, and elsewhere), instead of their normal constitution being maintained, will consequently have substituted some other than their healthy formation, in excess or in defect, as the case may be. Where so large and so important a viscus as the liver exists, we cannot suppose but that its functions are of the utmost importance. The many morbid states it displays without immediate fatal interference or death point otherwise; so, likewise, may it be said of every other organ of the human body, from the brain to the smallest cell, which may remain unsound throughout life to a greater or less extent. A great part of the way of diseases is as unknown. The want of access to medical libraries will, in the remarks I have made, be my excuse for the total absence of reference to authorities on this subject. Blood dyscrasia is a wide field, and its connexion with morbid growth, fatty fibroid, and other degenerations requires investigation.

A NOTE ON "TROPICAL ULCER."

BY GEORGE RANKING, M.D. CANTAB.,
SURGEON, 5TH BENGAL CAVALRY.

I HAVE adopted the above name for the form of ulcer which I am about to describe for two reasons: firstly, because it leaves open the question of causation; and, secondly, because, never having met with cases of ulceration exactly conforming to this type elsewhere, it has been my lot to see large numbers in tropical latitudes, under various names taken from the locality—e.g., "Delhi boil," "Meean Meer sore," "Scinde sore," &c. The ulcer commences usually as a small circumscribed patch of inflamed skin. This is attended with pain of varying intensity, but generally only amounting to burning or itching sensations. The skin on palpation is found to be boggy, with a zone of œdema surrounding it. Very soon there appears a dark central spot, which ulcerates, leaving a small perforation, through which issues a larger or smaller amount of thin

Digitized by Google

unhealthy purulent fluid. Quickly the edges of this perforation ulcerate away, and it is seen that the skin is undermined over the whole extent of the inflamed area. Eventually, when the whole of this skin has sloughed away, there is left a ragged ulcer with thickened edges and with a base of sloughing cellular tissue. The edges are much raised, so that the ulcer appears deeper than it really is. This ulcer partakes of the nature both of the irritable and indolent ulcer, inasmuch as it is sluggish, with indurated and elevated borders of more or less irregular outline, and surrounded with more or less œdema, according as it occurs in a dependent part or otherwise. It is also painful, often excessively so, the pain being sometimes so great as to be hardly bearable, at other times almost *nil*. In these accessions of pain there is almost always a marked tendency to periodicity. It is, however, in its healing that it presents one of its most peculiar features: a scaly-looking scab, which retards healing greatly if not removed, is apt to form over the ulcer. If, however, this be prevented, the edges of the ulcer gradually heal, with marked exfoliation of epidermis, which, if allowed to become dry, forms a ring of adherent horny scales, removal of which is generally attended with bleeding. The newly-formed skin round the edges of the healing ulcer, and also the skin of the ulcer when healed, show this scaling process for some time subsequently. A certain amount of pigmentation remains after the ulcer has healed; this in Europeans is of a bluish tinge, and in natives of India somewhat the same, making allowance for the difference of colour in the healthy skin. It is in no way comparable with, or liable to be confounded with, specific pigmentation.

In treatment these ulcers are peculiarly obstinate; all recognised modes of treatment by rest, position, strapping, Martin's bandages, aided by iodoform, iodine, carbolic acid, boracic acid, and what not, fail signally to effect the slightest improvement till the peculiar nature of the ulcer is recognised and made the basis for a system of treatment. And here, though I do not wish to discuss the etiology of these ulcers, I wish to remark, *en passant*, that without anti-malarial treatment these ulcers will never heal soundly, and that when once the patient is put upon largish doses either of quinine or arsenic, the simplest local treatment will suffice to effect a comparatively speedy cure. Of the local measures adopted for the cure of these ulcers, frog-skin grafting I have found most successful. The operation of "fringing" or snipping the edges round, with free division of the fibrous base of the ulcer, in long-standing cases, must precede all other local measures. My attention was first called to this method of treatment by a paper which was published towards the end of 1884 by Dr. Allen of Leadgate, co. Durham. The paper may be found at p. 875 of THE LANCET for 1884, dated Nov. 15th. I can fully corroborate all that Dr. Allen says in that paper, except that I have not found the frequent necessity for a series of grafts which he describes.

My cases had, with one exception, been in native soldiers. That exception was the case of an officer, who suffered from severe ulceration of the foot, off and on, for upwards of three years. Two visits to Europe cured the sore for a time, but it recurred each year on return to India. The officer in question suffered from marked malarial cachexia, and was very anæmic. After almost every drug had been tried, the real nature of the sore was appreciated, having been hinted at by the periodicity of the pain and occasional intercurrent attacks of ague. Treatment by quinine speedily brought about healthy action in the ulcer, and when this was sufficiently healthy to admit of grafting, frog-skin grafts were applied, and the ulcer speedily healed soundly and well. The resulting cicatrix was firm, sound, and appeared likely to remain so.

After this case the regiment with which I am serving was in Beluchistan, in a notoriously unhealthy district, where scurvy is endemic and ulcers of the kind now under consideration are extremely common. The men suffered greatly from these sores, and every officer in the regiment, with one exception, had several, either on the arms or legs. I went on leave in August, when these sores were just beginning to appear, and my place was taken by Surgeon Price, I.M.S.; his experience led him to the same conclusion at which I had arrived—viz., that to be successful in the treatment of this form of ulcer one must have recourse to either arsenic or quinine. When the regiment arrived at Meean Meer in February of the present year, after a year's service in Beluchistan, there were upwards of fifty men in hospital, fully one-half of whom had these "tropical ulcers." These were for the most part on the legs, a favourite place being the dorsum of the foot. They were all put upon quinine and iron, and the foot of course placed in the most favourable position. Many of these ulcers healed readily; but the more obstinate required grafting with frog-skin, after which they healed with astonishing rapidity. I have selected four cases from those treated.

Recruit M. S——, 4th Troop, was admitted to hospital on Jan. 30th, on the arrival of the 5th Bengal Cavalry from the line of march. He was anæmic, and evidently in great pain from a large ulcer on the dorsum of the right foot. He had had this ulcer some two months, it having appeared shortly before the regiment marched, but he had managed to march with the regiment, wearing the country shoe in lieu of his jack boot. The ulcer was as large as a crown-piece, deeply cupped, with high, sluggish, ragged edges. His general condition improved slowly, and by the end of February the ulcer, which had for a week previously been treated with a Martin's bandage locally, was in a fit state to graft. Six grafts from the belly of a frog were applied; healing was seen to be going on when the first dressings were removed on the fourth day, and proceeded uninterruptedly, being complete by March 15th. He was discharged to duty on April 12th, with a soundly healed foot, able to wear his jack boots and perform all his duties with efficiency.

The other three cases are as follows:—

Sowar No. 112. S. C——; admitted on Feb. 4th; grafted on March 2nd; discharged to duty on April 17th.

Sowar No. 500. S. S——; admitted on Feb. 5th; grafted on March 2nd; discharged to duty on March 29th.

Sowar No. 275. G. S——; admitted on Feb. 5th; grafted on March 1st; discharged to duty on May 7th, 1886.

These are a few of the cases. The point which has forced itself upon my notice is that, once the essentially malarial nature of these ulcers is recognised, they prove as amenable to treatment as any other ulcer. If, on the other hand, one ignores, whether from prejudice or other cause, this malarial factor, the "tropical ulcer" proves not only a most stubborn foe to the medical officer, but a most fruitful source of loss of service to the State.

Meean Meer.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

ST. THOMAS'S HOSPITAL.

A CASE OF INGUINAL ANEURYSM SUCCESSFULLY TREATED BY LIGATURE OF THE EXTERNAL ILIAC ARTERY; WITH POPLITEAL ANEURYSM IN THE OPPOSITE LIMB, TREATED BY COMPRESSION AND GALVANO-PUNCTURE. NECROPSY, EIGHTEEN MONTHS AFTER OPERATION; REMARKS.

(Under the care of Mr. WILLIAM ANDERSON.)

IT is seldom that we are able to publish a case in such complete form as that recorded below, and the unusual condition of the inguinal aneurysm as found post mortem and illustrated by the diagram is very interesting. How far the introduction of the needles into the sac and the passage of the electric current through them may have contributed to the successful treatment of the popliteal aneurysm it is difficult to say, so many cases apparently similar having been cured by simple digital compression. The special precautions taken in the management of the needle punctures are worthy of note, and we shall be glad to see the records of other cases of aneurysm treated in a similar manner. For the notes of the case we are indebted to Mr. R. V. Solly, dresser.

The patient, a carman, aged forty-two, was admitted on July 20th, 1885, with the following history. Health always good, but habits rather intemperate. He was not aware that he had had any venereal disease, but he suffered from an

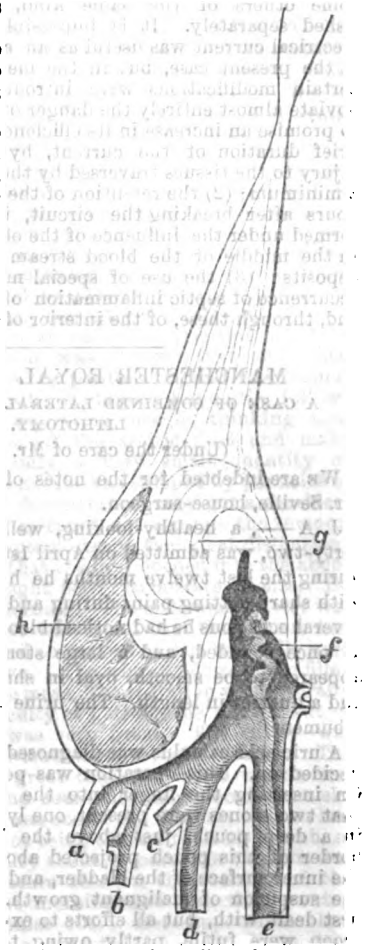
Digitized by Google

abscess in the right groin seven years ago, and three years later was laid up for three weeks with acute epididymitis. There was no history of secondary manifestations of syphilis. Seven or eight weeks before admission he observed a pulsating swelling in the right groin. As this enlarged and at length became painful, he attended at the hospital.

On examination a large aneurysm was found in the right groin. It was pear-shaped, about three inches and a half in length and two inches in its greatest transverse diameter, and the narrow upper extremity extended for a short distance beyond Poupart's ligament into the pelvis. Further exploration of the arterial system led to the discovery of a second aneurysm, about the size of a hen's egg, in the upper half of the left popliteal space. The patient had not previously been aware of the existence of this tumour, but thought it might have been caused by his habit of riding on the cart with the leg hanging over the side, the ham resting against the edge of the vehicle. The general health appeared to be fairly good, and the heart and lungs were normal. The left pupil was larger than the right, both however acting to light, and on convergence.

Under the influence of rest the man improved during the first week of his stay in the hospital, but at the end of this time the inguinal aneurysm began to enlarge rather rapidly, and the limb became swollen and painful.

On July 31st Mr. Anderson tied the right external iliac artery. The vessel was exposed under antiseptic precautions, by means of an incision three inches long, parallel to and an inch above Poupart's ligament. A ligature of stout carbolised catgut was applied about an inch and a half above Poupart's ligament, and after the insertion of a drainage tube the wound was closed and dressed with iodoform gauze and salicylic wool. The pulsation of the aneurysm was completely arrested immediately after the tightening of the ligature. The surface temperatures of the lower extremities after the operation were as follows:—Two hours after: left, 95·2°; right, 90·4°. Five hours after: left, 97·8°; right, 95·2°. Nine hours after: left, 97·4°; right, 98°.



During the next few days the right leg was generally half a degree or a degree cooler than the left, but on one or two occasions its temperature rose somewhat higher than that of its fellow. The equilibrium was permanently established by the end of a week. The wound healed by first intention, and no unfavourable symptoms arose until nearly two months after the operation, when the patient, having undergone treatment for the opposite limb, was allowed to get up. A recurrent pulsation was then observed in the apparently cured aneurysm. The impulse gained in strength during the next fortnight, after which it remained stationary. The tumour, which had shrunk after the ligature of the artery, did not become larger after the reappearance of the pulsation.

The treatment of the popliteal aneurysm was commenced on September 3rd. Digital compression of the common femoral was started at 2 P.M.; an hour later two Duncan's needles were introduced into the sac and connected with the poles of a Stohrer's battery; a current from sixteen cells was passed for five minutes, after which the needles, carefully packed with antiseptic wool, were left *in situ*. On the following day, at 10.15 A.M., the compression was discontinued and the needles were withdrawn. Pulsation was found to be completely arrested. The temperature of the limb during the next twelve hours sank four or five degrees Fahrenheit below that of the opposite leg, but gradually rose again to the normal level on the following day. The needle punctures showed no signs of irritation, and were closed by the end of the second day after the cure. The patient was allowed to leave his bed on the 20th, and was shortly afterwards discharged.

During the next few months the man showed himself from time to time, and appeared to be in very good health. He was following the employment of a tram conductor, and said he was able to do his work without difficulty. The pulsation in the inguinal tumour persisted, but there was no increase in its force, and the sac had not enlarged.

On the 10th of January last the patient, who had been absent for over a year, was brought to the hospital in a state of extreme prostration, suffering from severe cough and dyspnœa, with signs of aneurysm of the arch of the aorta. No change had taken place in the inguinal aneurysm, which still pulsated, but the popliteal tumour was smaller, and remained quite solid. The thoracic symptoms made rapid progress, and death occurred on the evening of the 13th.

At the post-mortem examination a large sacculated aneurysm was found on the right side of the ascending part of the arch of the aorta; the lungs were congested, and showed patches of broncho-pneumonia; and the large arteries were extensively diseased. The heart walls and valves were normal, and no evidence of pre-existent syphilis was anywhere to be seen. The two aneurysms operated upon by Mr. Anderson were removed entire. The condition of the parts was as follows:—The external iliac artery at the seat of ligature was reduced to a solid cord of about one-tenth of an inch in diameter, and the canal above this point was filled with clot as high as the bifurcation of the common iliac, and below as far as the aneurysmal sac. The aneurysm itself was of pyriform shape, about two inches in length, and involved the whole circumference of the artery down to the origin of the profunda; the lower part of the tumour was dilated into a kind of fundus, with which were connected, separately, the superficial femoral, the profunda (joined immediately below by its external circumflex branch), the internal circumflex, and a large muscular branch. On section, the sac was found to be almost filled with coagulum, partly soft, reddish, and friable, and partly pale, firm, and laminated; but at the lower and back part of the aneurysm was an irregular cavity or sinus, into which opened the vessels named (see diagram), and which was occupied in part by a string-like coil of decolourised fibrin that extended below into the common femoral. The popliteal aneurysm offered nothing special for notice. It was of about the size and shape of a small chestnut, and sprang from the inner and back part of the vessel, about an inch above the bifurcation. The artery was impervious as low as the origin of the anterior tibial, and the vein was obliterated to a corresponding extent. The sac was filled with friable clot, without any fibrinous laminæ, and appeared to have originally communicated with the main vessel by a rather small aperture. The popliteal artery of the opposite side was somewhat dilated above its bifurcation, and nearly opposite to this the vein was obstructed by a decolourised thrombus of old date.

Semi-diagrammatic outline of aneurysm and vessels. *a*, Internal circumflex. *b*, Muscular branch of internal circumflex. *c*, External circumflex. *d*, Deep femoral. *e*, Superficial femoral artery. *f*, Cavity with thread-like coil of fibrin. *g*, Laminated fibrin. *h*, Soft clot.

Remarks by Mr. ANDERSON.—Recurrent pulsation in the sac of a femoral or inguinal aneurysm after ligature of the external iliac artery has been recorded in several instances; but this case presents certain peculiar features of its own. An examination of the diagram will show that a complete consolidation of the tumour would almost inevitably have entailed gangrene of the limb, as the principal collateral stream could only reach the superficial and deep femoral vessels by passing through the fundus of the sac. So long as the patient was recumbent and at rest the force of the

Digitized by Google

in-coming current was not sufficient to give any noticeable impulse to the tumour, but as soon as exercise was resumed pulsation reappeared, and a secondary cavity of considerable size seems to have been formed at the expense of the soft coagulum. At a later stage the dimensions of the cavity underwent progressive diminution by the deposit of laminated fibrin upon its walls, and had the patient lived longer the obliterative process would probably have advanced much further, although it is unlikely to have ever become complete. At one period in the post-operative history of the tumour the development of a secondary aneurysm, having the same tendencies as the first, was more than a possibility. Had this occurred, the treatment of the condition would have been a very serious problem.

The plan adopted for the cure of the popliteal aneurysm needs only a brief allusion here, as the case, with some others of the same kind, will shortly be published separately. It is impossible to say how far the electrical current was useful as an adjunct to compression in the present case, but in the method of its application certain modifications were introduced which appear to obviate almost entirely the danger of galvano-puncture, and to promise an increase in its efficiency. There were (1) the brief duration of the current, by which precaution the injury to the tissues traversed by the needle was reduced to a minimum; (2) the retention of the needles *in situ* for many hours after breaking the circuit, in order that the clot formed under the influence of the electricity might be held in the middle of the blood stream as a nucleus for fresh deposits; (3) the use of special measures to prevent the occurrence of septic inflammation of the needle punctures, and, through these, of the interior of the sac.

MANCHESTER ROYAL INFIRMARY.

A CASE OF COMBINED LATERAL AND SUPRAPUBIC LITHOTOMY.

(Under the care of Mr. HARDIE.)

WE are indebted for the notes of the following case to Mr. Seville, house-surgeon.

J. A——, a healthy-looking, well-nourished man, aged forty-two, was admitted on April 1st. The history was that during the last twelve months he had been much troubled with sharp cutting pains during and after micturition. On several occasions he had noticed blood in the urine. He was at once sounded, and a large stone was readily felt; it appeared to be smooth, oval in shape, and about an inch and a quarter in length. The urine was acid and free from albumen.

A uric acid calculus was diagnosed, and lateral lithotomy decided on. This operation was performed on April 2nd. On inserting the finger into the bladder, it was found that two stones were present, one lying free, and the other in a deep pouch, just above the left tuber ischii. The border of this pouch projected about half an inch above the inner surface of the bladder, and was so hard as to raise the suspicion of malignant growth. The loose stone was first dealt with, but all efforts to extract it by forceps and scoop were futile, partly owing to the impossibility of laying hold of it in the long axis, and partly owing to the other stone being dragged at the same time towards the opening and blocking the way. Attempts were then made to dislodge the encysted stone, but these were likewise unavailing. The question of breaking the stones with the lithotrite and extracting the fragments by the perineal wound, or of opening the bladder above the pubes, was then considered, and the latter operation decided on. A sound was therefore passed into the bladder by the perineal wound, and made to project above the pubes. An incision about three inches long was made in the middle line just above the symphysis, and careful dissection carried on till the bladder was reached. Two strong threads were then passed in a longitudinal direction and about half an inch apart through the wall of the bladder, which was rendered prominent by means of the sound, and the viscus was opened between them. There was now no difficulty in seizing first the one and then the other stone with lithotomy forceps and extracting them. A lithotomy tube was introduced into the perineal opening, and the suprapubic wound was simply dusted with iodoform and lightly covered with a dry absorbent dressing. The stones were very similar in shape and size, being oval or somewhat triangular in outline, with flattened surfaces. They were found to weigh 2 oz. 80 gr. and 2 oz. 50 gr. respectively.

The patient very rapidly got over the effects of the chloroform and the shock of the operation. In the course of the next few days the urine became very foul, and the bladder was therefore washed out twice daily, through the perineal opening, with a warm saturated solution of boracic acid. Except for slight pains in the lower part of the abdomen and some flatulence the patient expressed himself as feeling quite well. On the 5th urine began to flow from the suprapubic wound, and a few days later the greater part escaped by it, scarcely any coming by the perineal tube, which was therefore removed. On the 23rd a little urine for the first time escaped by the urethra. As the perineal wound had now almost closed, the bladder was washed out by passing a tube into the suprapubic opening and allowing the fluid to escape by the urethra. During the next month, except a little improvement in general health, no appreciable progress was made; but towards the end of May the suprapubic wound began steadily to contract up, and by the end of the month was too small to admit the insertion of the tube to wash the bladder; it did not, however, finally close till three weeks later. The interior of the bladder was examined with a sound, and the part corresponding to the situation of the pouch was felt to be very rough and irregular. It was supposed that much of the discharge was occasioned by its sluggish filling up and healing. During the early part of June a solution of nitrate of silver was applied to the interior of the bladder once daily. The strength used was five grains to the ounce at first, gradually increased to ten. Under this treatment the cystitis rapidly improved, and with it the general health. The patient went home on June 24th.

DEVON AND EXETER HOSPITAL.

THREE CASES OF COMPOUND FRACTURE OF THE SKULL; TREPHINING; RECOVERY.

(Under the care of Mr. BELL.)

CASE 1.—T. T——, aged twenty-six, a miner in a stone quarry, was admitted on Jan. 1st, 1887. Whilst he was at work a large piece of rock fell on his head, and he became insensible, but regained consciousness prior to admission. On examination, a wound extended downwards from the top of the left side of the frontal bone to the upper edge of the malar bone, at the upper part of the wound over the left temple. The skull was fractured and driven in, the cavity being about the size of a florin; the orbital portion of the frontal bone was loose; there were some loose fragments of bone lying in the wound, and a squarish piece of bone, measuring ¾ in. by ½ in., driven down upon and depressing the brain. Under chloroform, Mr. Bell removed the loose pieces of bone, but was unable to raise the piece which was depressing the brain. He therefore enlarged the wound upwards, and, trephining the frontal bone at the upper edge of the fracture, removed the depressed portion, which had become wedged under the edge of the sound bone; the dura mater was uninjured, and the brain immediately regained its normal position. The wound was washed out with warm weak carbolic solution, and brought together with horsehair sutures, a drainage tube being inserted and iodoform and Gamgee dressing applied. The patient was then placed in bed, and an ice-bag applied.—Jan. 2nd: Temperature 99°; pulse 88. No pain in the head. Was sick twice in the night (chloroform?).—3rd: Temperature 98·4°; pulse 80. No sickness. The drainage tube was removed; dressing as before. From this time he made an uninterrupted recovery, the wound healing by first intention. Before finally leaving the hospital he was fitted with a light celluloid guard

CASE 2.—T. C——, aged forty-three, a labourer, was admitted on March 24th, 1887. He had, about three hours previously, fallen into a stone quarry, a distance of thirty feet, pitching on his head. On admission there was a severe lacerated scalp wound over the posterior superior region of the left parietal bone. On passing the finger into this, a depressed fracture was found. There was also a scalp wound at the back of the head. The left arm was much bruised and very painful; the right arm completely para-

Digitized by Google

lysed and very cold. Pupils normal; pulse regular at both wrists, but somewhat slow. He was fairly conscious, and had not vomited. Temperature normal. Under chloroform Mr. Bell enlarged the wound, making a T-shaped flap. On turning back the flap a depressed fracture of the left parietal bone was found, and a piece of bone measuring 1 in. by ½ in. was seen driven in upon the brain. A large-sized trephine was applied at a point about five inches above the front of the left ear, five inches above the centre of the left orbital ridge, and rather more than one inch to the left of the central line; the depressed bone was split into plates and driven under the sound bone; these were removed with forceps, and the depressed edges of the sound bone elevated. The dura mater appeared uninjured. The area of bone removed measured about 2 in. by 1 in. Dressing same as in Case 1. After operation, before removal from the room, the right arm became bathed in sweat, and then normally warm.—March 25th: Has had a fairly good night; no sickness, and is quite conscious. Pulse and temperature normal. Can move the right hand slightly.—26th: Dressing re-applied and drainage tube removed; arm recovering.—April 1st: Wound re-dressed; no discharge. Movement of arm almost regained. From this date the patient rapidly recovered, and left the hospital wearing a celluloid shield, the grasp and movement of the right arm being normal.

CASE 3.—A. N——, aged fourteen, was admitted on May 21st, 1887, at 6.30 P.M., having, an hour and a half previously, been knocked down by a railway engine. On admission the patient was unconscious, and lay perfectly still, breathing heavily. When touched or spoken to, he became very noisy and violent. The right cheek and parts around it were very much bruised and swollen, and there was a small oblong wound just above the right eyebrow. On passing a probe into this, a depressed fracture was felt. There was free bleeding from the nose, but none from the ears. His pulse was feeble and slow, and the skin generally cold. Under chloroform, Mr. Bell enlarged the wound longitudinally, and made a vertical incision of about an inch upwards from the centre; the flaps were turned back and bone exposed; a piece of the frontal bone, measuring 1 in. by ½ in., was found fractured and depressed. The trephine was applied to the frontal bone above and to the inner side of the orbit; the depressed and loose bone was removed. The dura mater appeared uninjured. There was some free bleeding. The wound was treated and dressed as in the previous two cases. He made an excellent recovery.

Remarks by Mr. BELL.—These cases were all operated on immediately on their admission to the hospital. This I think of great importance as to successful result, together with the perfect cleansing and drainage of the wound; and I am also convinced that the application of the ice-bag to the head is an essential part of the after treatment.

STANLEY HOSPITAL, LIVERPOOL.

A CASE OF DISLOCATION OF THE HIP IN A CHILD AGED FIVE.

(Under the care of Mr. KELLETT SMITH.)

WE are indebted to Mr. G. P. Newbolt for the following notes.

Charles R——, aged five, was admitted late on May 10th. Ten minutes before admission he had fallen off a waggon whilst playing in a barn, his leg getting twisted under him as he fell.

On admission the child was unable to walk, and complained of pain in the left hip. On examination, the left limb was found to be flexed, adducted, and rotated inwards; there was no crepitus, but the head of the bone could be felt on the dorsum ilii, and the limb was comparatively fixed. On standing the child on the sound limb, the left at once assumed the characteristic position of a dislocation on the dorsum. There was one inch shortening. Having laid him on his back, the limb was flexed, abducted, and rotated outwards. The head slipped in with an audible click, and the deformity at once disappeared, the movements of the joint being perfectly natural. The child seemed much relieved, and at once ceased crying.

The little patient was kept lying on his back for two weeks with a Thomas's hip splint applied. The splint was then taken off, and at the end of three weeks he left the hospital walking perfectly well.

Remarks by Mr. NEWBOLT.—The case is interesting from the rarity of the accident at so early an age, fracture of the shaft being more common. The ease with which it was reduced is also worthy of notice. This, I suppose, may be partially accounted for by the short interval (about fifteen minutes) between the displacement and its reduction. No anæsthetic was used.

Medical Societies.

ACADEMY OF MEDICINE IN IRELAND.

Ovarian Tumour.—Report of Rotunda Hospital.

AT a meeting of the Obstetrical Section held on June 10th, Dr. A. SMITH exhibited a Fœtus of six months. It was surrounded by membrane and had the placenta attached. The most interesting part of the specimen was its posture, indicating how the child had lain in the uterus. The extremities were folded together, the cord was round the neck, and one foot was almost touching the nose. Meconium was coming away from the anus at the time of birth.

The PRESIDENT exhibited an Ovarian Tumour which he had removed from a woman, aged forty years, who had had six children and one abortion. Shortly after her last pregnancy she began to feel a pain at the lower part of the abdomen near the labia; and in a year afterwards a swelling had come on. Twelve months ago she came to the Rotunda Hospital and was advised to submit to an operation, but would not do so and left. Recently she came back to the hospital, being swollen to an enormous size and unable to walk. On examination it was obvious that there had been a large effusion into the peritoneum, and the tumour could hardly be made out. He tapped her on the following morning with an aspirating needle, thinking that he would be able to get off the ascitic fluid and make out the tumour, but only a very small quantity of fluid came away, as the needle was stopped by particles of thick, jelly-like matter. Nevertheless, they got a considerable quantity out, but they could not aspirate the tumour. She had no serious symptom except the great distension; and as it was obvious that the cyst opened into the abdominal cavity, it was thought better to operate at once. He did so on the previous morning. The abdominal cavity was full of viscid stuff, and it was found that the tumour had burst at one side. He tried to remove it, but the walls were so thin that it broke down. The whole abdomen was filled with the viscid, jelly-like mass. The operation was naturally a long one, and the difficulty of getting the matter out of the abdominal cavity was very great. The cavity was thoroughly washed out with a weak carbolic solution. The distension had been so great that the whole vagina was completely prolapsed, and could not be replaced when she lay in bed. The pedicle was one of the thinnest that he had seen for a long time, not being thicker than his thumb, so that there was no difficulty about it once the tumour was removed. The temperature rose on the evening of the operation to 101°; that morning and also that evening it was 98°, and her pulse 104. Her appearance had improved since she was operated on.—Dr. KIDD said he had seen three or four cases in which tumours had burst into the cavity of the peritoneum, and the majority of them did not turn out satisfactorily. The last case of it that he saw he described at a meeting of the old Obstetrical Society. It was complicated with pregnancy, and Sir Spencer Wells was brought over and operated on the lady, but she died on the sixth day. Most of these cases were capable of being diagnosed beforehand; and the inversion of the vagina in them was very remarkable. In cases of ascites Douglas' space was generally protruded; but he did not think that occurred in cases of ovarian dropsy.

Dr. JOHN L. LANE then submitted the report of the Rotunda Hospital for the three years ending Nov. 3rd, 1886.—Dr. KIDD said Dr. Lane was to be congratulated on this report, which was a satisfactory one in every respect. The most important feature in it was the record of patients followed for five or six weeks after they had left the hospital. It was the fair and right way of estimating the mortality of puerperal conditions. During the first 100 years of the existence of the hospital the mortality,

Digitized by Google

as stated by Johnston and Sinclair, had been 1·21 per cent.; and during that period antiseptic precautions and treatment were not known. Perhaps if the cases had been followed and counted, as had been done, according to the present report, the mortality would have been greater. It was curious that during the mastership of Dr. Collins the mortality in the hospital from all causes was 0·54 per cent., being less than half the mortality recorded in the present report. They might be sure that all the cases that occurred during Dr. Collins's time were fairly cured; but there was no evidence in his book, as far as he remembered, that the cases were followed as they had been during the last three years. During his time 10,785 patients were delivered, and the total mortality was 0·96 per cent.; and during the last four years of his mastership the mortality was 0·54 per cent. Dr. Macan had succeeded Dr. Atthill in the mastership. During the last few months of Dr. Atthill's mastership there was a remarkable outbreak of puerperal fever in the hospital. The history of puerperal fever in the hospital had been always this: First there came an epidemic with a large resulting mortality; after it subsided they had a freedom from puerperal fever and a gradual decrease in the deaths for three or four years. Dr. Macan's first report did not show a death from puerperal fever. Now they were having an increase in the number of deaths; and he hoped that it would prove the omen of a future corresponding diminution. Dr. Collins entered upon his mastership after an outbreak, and for three years the mortality was low, though considerable. Afterwards, for four years, there was not a case of puerperal fever, and there came the mortality from all causes of 0·54. Dr. Ivory Kennedy then entered upon the mastership, and in his first year there was a furious outbreak, with a mortality larger than had ever been known before. He did not think the immunity from the disease at those intervals had been due to any extra precautions, but rather to the natural history of the disease. He did not say a word against antiseptic treatment; on the contrary, he believed in it, recommended it, and followed it as far as his lights enabled him to do. But it was necessary to look facts in the face; and one of these was the natural history of disease.—Dr. BYRNE observed that the report contained no allusion to the mortality of the children during the three years. Many years ago, in Dr. Clarke's time, the condition of the Rotunda Hospital must have been very bad; puerperal tetanus was then quite common in it. Dr. Clarke's attention was directed to the unsatisfactory condition of the place, and he improved it as far as was in his power. Great and remarkable improvements had been made by succeeding masters; but Dr. Macan might be looked on as the pioneer of antiseptic remedies. Yet he appeared to have abandoned them in this report. He appeared to be a good deal in accord with the tendency of the present day, which was to discard all those remedies. During three years of Dr. M'Clintock's mastership—from 1842 to 1845—there were 6664 deliveries; and during Dr. Shekleton's mastership of seven years there were 13,748 deliveries. That meant that during both these masterships the wards had been more crowded than they were during Dr. Macan's mastership. The present master of the hospital had gone on doing the best he could; but there was something more in the facts than could be explained by antiseptic treatment. Antiseptics had been multiplied, yet still puerperal disease remained. Therefore, it appeared to him that antiseptic treatment had proved a failure to a considerable extent. Of the number of patients who died eighteen were primiparæ and twenty-five were multiparæ of from two to five and six births each. This was a little different from the ordinary reports of maternities, which, as a rule, showed that the mortality was greater in primiparæ.—Dr. HORNE considered the report a most valuable one. As regarded the question of mortality, the results given in the present report could hardly be compared with those of the [illegible] the century; for amongst the old rules of the hospital was one that the master was to "endeavour to keep patients at least five days in hospital after their confinement"; consequently the period of observation was altogether different. The statistics of the present report showed that in 1883 and 1884 there were 175, in which the temperature did not exceed 100·4°; that in 1884 and 1885 the number with such temperature decreased to 94; and that in 1885 and 1886 there was a further fall to 93, which circumstance showed that while the mortality had somewhat risen, the general health of the hospital had improved.—Dr. DOYLE said he looked on this report as the most reliable one that he had ever heard in connexion with the Rotunda Hospital. Hitherto each writer of a report had gone on a different system of making up his statistics; but until one uniform system should be adopted by all, it would be impossible to make reliable comparisons with respect to the mortalities in the various periods.—The PRESIDENT said he had not looked up former mortalities; but in some former reports he had seen as many deaths recorded in a month as had taken place latterly in the Rotunda Hospital in a year. The epidemic theory might be offered as the explanation of that; but he would express his absolute disbelief in any such thing as an epidemic of puerperal fever. There might be a lot of cases in the hospital at a particular time, because even one case was a source of danger; but he repudiated the idea that there could be anything in the air to cause it, or that anything was to come in the third year because it had not come for two years before. He would not attempt to compare present statistics with those of a hundred years ago. They did not call the same thing puerperal fever then that was now known by that name; and it was not now known what former conditions were. If hands and instruments were kept clean he would go so far as to say that puerperal mortality would be almost *nil*. What they had to do was to be on their guard with single cases of puerperal fever, for if there was any want of care in respect of cleanliness or antiseptic precautions, a whole ward might become full of it before they knew where they were. The only difficulty that he felt as regards his belief in antiseptics was how they got rid of puerperal fever without them in old times. In some cases it was more difficult to apply them than in others; but on the whole he thought that antiseptics were the very centre and essence of midwifery nowadays.

The Section then adjourned.

Notices of Books.

The Mineral Waters of Vichy, and the Diseases in which they are indicated, followed by a Sketch of some of the principal Excursions in the Environs. By Dr. C. E. CORMACK. Pp. 375. London: J. and A. Churchill. 1887.—The author of this work states that, while the number of visitors to Vichy has of late years been steadily increasing, the number of English tends to decrease, and is considerably less than it was ten years ago. He has been induced to compile the present volume in the hope of checking this tendency by directing attention to the great efficacy of the waters in the treatment of a number of complaints. The work is divided into two parts: the first giving a description of the various springs (thirty-one in number), and the diseases in which they are generally found beneficial; and the second affording all the necessary information respecting the means of reaching Vichy, the town itself, the thermal establishment, and the different places of interest in its environs or within easy reach of it. The first part might again be subdivided into two: the first section giving a detailed account of the different springs, the mode of using the waters, and the hygiene and diet required during treatment; and the other, a description of the diseases treated at Vichy. In the preface the author has stated that the book "has been composed not so much for the medical profession as for the public; and we have endeavoured to explain in popular language where the thermal treatment is indicated, and how the waters operate." In this point of view we cannot but think that the chapter on the diseases—extending over 124 pages—is a great mistake, and likely to do much more harm than good to the invalids who read it. With that exception the work will be found of value, furnishing, as it does, much useful information respecting Vichy and its waters. If a second edition is called for, we would strongly recommend the author to excise the chapter, or at least to cut it down to a very moderate size by the omission of a great deal of the purely professional matter. There are

Digitized by Google

two maps with the book—one of the town, and the other of the environs of Vichy. The latter is merely a road map, and is defective in not showing the mountain ranges. There is also a good index to the book.

The Climate of Llandudno. By JAMES NICHOL, M.D., late Medical Officer of Health. Manchester and London: John Heywood.—In this pamphlet Dr. Nichol discusses the scenic and climatic attractions of Llandudno and their applications to cases of disease. To those who are familiar with this charming Welsh watering place it will not be surprising that the writer should make out a very good case; but his words would carry more weight if they were less of the nature of an unqualified panegyric. The facts adduced prove satisfactorily that Llandudno has a climate of considerable equability and comparative dryness, and that the soil, drainage, and water supply all conduce to constitute it a health resort of decided value. We cannot, however, share Dr. Nichol's surprise that the mean temperature of Llandudno should be as high as that of Eastbourne, Bournemouth, or Torquay, as it is well known to practical meteorologists that in these islands, owing to the influence of the Gulf Stream, the isotherms run north and south, rather than east and west. Thus the little island of Monach in the Hebrides has actually almost as high a mean temperature as Jersey. These facts are, no doubt, commonly ignored, and it is not a work of supererogation to remind the public that the winter at Llandudno is as mild as at some of the most favoured spots upon the south coast. While Dr. Nichol's meteorological facts are marshalled in a workmanlike fashion, we can hardly say the same about his observations regarding the influence of the climate of Llandudno upon disease. He says: "In regard to the class of diseases and conditions of the system to which the climate of Llandudno is adapted, their name is legion. It is beneficial in almost all cases of simple debility, whether general or local, constitutional or inherited, or the result of acute or chronic disease." Vague statements of this kind are of little value. If Dr. Nichol has not met with any cases of debility which are injuriously affected by sea air, we must regard his experience as exceptional. While unable to acquiesce in all Dr. Nichol's enthusiastic eulogies, we are of opinion that the merits of Llandudno, both as a summer and winter resort, are exceptional, and we commend them to the attention of the profession.

A New Basis for Chemistry: a Chemical Philosophy. By THOMAS STERRY HUNT, M.A., LL.D. Cantab., author of "Chemical and Geological Essays," &c. Boston: Cassino. London: Trübner and Co. 1887.—The author of this book, a distinguished American man of science, has been known for many years as an opponent of the atomic hypothesis in chemistry. He now gives us, in a series of essays founded on the latest observations of chemists and physicists, an alternative hypothesis in a coherent form. No true chemist accepts Dalton's great generalisation as an expression of absolute truth, but merely as a convenient and more or less probable mode of accounting for facts. There are many difficulties in the way of the current views of chemical constitution and change, and every inquirer into truth, even if he is not ultimately convinced, will study with interest and profit any new hypothesis which offers a solution of the difficulties. It is not in our province, and would take far too great a space, to discuss Dr. Sterry Hunt's contribution to chemical theory. We can only indicate in a few words his line of argument, and leave those of our readers who are interested in scientific speculation to judge the book for themselves. Matter, according to Dr. Hunt, is homogeneous and destitute of ultimate particles. Each kind of matter is a species distinct in itself, but subject to metamorphoses such as are represented by the solid liquid and gaseous conditions, allotropic and polymeric varieties, and the like. Each species is produced by the integration or disintegration of other species, and he quotes and adopts the definition of Hegel, that "the chemical process is an identification of the different and a differentiation of the identical." Each kind of substance is neither an element nor a compound, but a species. The species from which no other species can arise by mere differentiation is what we call an element. The elements, like all other species, are formed by a genesis such as Mr. Crookes has recently suggested, and, finally, chemism is not to be confounded with dynamic agencies. "It is one of the manifestations of an energy pertaining to matter, which inclines it to integration or disintegration, as conditions favour the one or the other mode of change." This very crude sketch may convey some idea of the new chemical philosophy. It is supported by many ingenious arguments, among which those derived from the law of volumes are perhaps the most important; but it must be admitted that much still remains unexplained, and that the whole scarcely rises above the rank of an able and interesting speculation. As such we welcome it. Time will show whether it will prevail over Epicurus and Dalton, but in any case it is sure to assist in scientific thought.

A Manual of Veterinary Hygiene. By FRED. SMITH, M.R.C.V.S. Pp. 477. London: Baillière, Tindall, and Cox. 1887.—This is a work which cannot fail to prove useful and interesting to all who have to do practically with animals, and especially with horses. The author is Professor of Veterinary Hygiene in the Army Veterinary School at Aldershot, and has had the advantage of being trained in the Laboratory of Hygiene at Netley under the late Dr. Parkes, and has also worked there under Dr. De Chaumont. In this volume he has discussed at some length the principal conditions likely to affect the health of animals, and the measures necessary to maintain them in an efficient state. The chapters on stable construction, ventilation, food, and the eradication of epizootic diseases appear especially to deserve careful study. The chapter on individual hygiene is also very good, but is confined to that of horses alone; it might have been very advantageously extended to other animals. The value of hygienic measures is clearly shown by the greatly reduced death-rate and casting of our army horses in consequence of the attention paid to the sanitary conditions in which they are kept. "It has been publicly recognised that we have practically banished diseases which, before our time, decimated regiments; that we have prolonged the useful life of the horses of the army, and have placed them at the head of all others for freedom from diseases, and general fitness for work." In the French army, which, in this respect, is still behind ours, the adoption of sanitary measures "effected a saving of £90,000 per annum in the purchase of horses alone." There is still much room for improvement in the hygienic conditions of horses employed in civil life, and even more in those of other cattle. We trust that Mr. Smith's book may exercise a beneficial influence, by calling attention to the pecuniary advantages arising from a moderate expenditure in this direction. Another important matter which he discusses, and which seems to require great modification, is animal transport by sea. We strongly recommend the book to all who are interested in horses and other cattle, or who desire to promote their humane treatment. It has the advantage of a copious index.

Lehrbuch der Allgemeinen und Speciellen Pathologischen Anatomie. Von Dr. ERNST ZIEGLER. Zwei Bände. Fünfte Auflage. Erster Band: Allgemeine Pathologische Anatomie und Pathogenese. Zweiter Band: Specielle Pathologische Anatomie. Jena: Gustav Fischer. 1887. (*Text-book of General and Special Pathological Anatomy.* By Dr. ERNST ZIEGLER. Two Vols. Fifth Edition. Vol. I.: General

Digitized by Google

Pathological Anatomy and Pathogenesis. Vol. II.: Special Pathological Anatomy.)—The fifth edition of a work so widely known as Professor Ziegler's Text-book of Pathological Anatomy needs no introduction to favourable notice; still it must be remarked that, in spite of the rapidity with which one edition has followed on the steps of another, the author has found time and expended much pains to improve and amplify his book. Those who are familiar with Macalister's excellent translation will find in the present edition many improvements. There is not merely a rearrangement of the subjects, so that the work presents now a very systematic character, but the number of illustrations, the vast majority of which are original, has been greatly increased, and considerable additions have been made to the text. Although the work has thus increased in bulk, there have been certain curtailments—e.g., in the sections on the organs of special sense. The first volume deals solely with general pathological anatomy, and is not one quarter the size of the second, which embraces the subject of special pathological anatomy, the whole work containing upwards of 1500 pages (large octavo) and 703 illustrations. In the first volume we find very material additions. Thus the introductory chapter has been rewritten, and now comprises a succinct account of the febrile process. The second chapter is entirely new. It deals with etiology, the introduction of which into a pathological text-book is a welcome sign of the broadening tendencies of modern inquiry. In this chapter are discussed the operation of external agents in causing disease, the inter-relations of morbid processes in the several tissues, the subjects of metastasis and embolism, disposition and immunity, inheritance and malformation; but the detailed discussion of malformations, which originally opened the work, is now relegated to a later place—viz., after tumours have been dealt with. It will be noticed also that the sections treating of specific new growths have been transferred from the chapter on inflammatory processes to that on bacteria. As may have been expected, this last-named chapter has been subjected to thorough revision and extension, so that it forms a complete account of pathogenic bacteria, illustrated by numerous coloured illustrations. The second volume also shows many evidences of careful revision, and covers the whole ground of special pathological anatomy. The only portions of the work which are not by Prof. Ziegler are the sections on the diseases of the organs of vision and hearing, which are contributed by Drs. Haab and Wagenhäuser.

The Journal of Anatomy and Physiology. Conducted by G. M. HUMPHRY, Sir WM. TURNER, and J. MCKENDRICK. Part 3, Vol. XXI. April, 1887.—This is the third part of the first volume of a new series. May we suggest to the editors the great value that would be possessed by a thoroughly good index to the first twenty volumes. Vast stores of knowledge are concealed and are practically lost in these volumes; and all are aware of the authority that attaches to the numerous memoirs they contain, since many of them have been written by the ablest biologists of this country during the last twenty years, the first volume having appeared in 1866. It would not be a very troublesome task to combine in literal order the indices to the second volumes as they have been already published. The present part contains:—1. J. W. Fraser: Memoir on the Action of Infused Beverages on the Peptic and Pancreatic Digestion of the chief Dietetic Proximate Principles. 2. Thomas Shore: Relations of the Mammalia to the Ichthyopsida and Sauropsida. 3. Henry Bewley: On the Changes produced in the Lungs of Sheep by a Parasitic Worm (Strongylus filaria). 4. James Oliver: Menstruation; its Nerve Origin, not a Shedding of Mucous Membrane. 5. W. Arbuthnot Lane: Evidence of Labour from examination of Skeleton. 6. M. Paterson: Morphology of Sacral Plexus in Man. 7. A. Macfadyen: Behaviour of Bacteria in the Digestive Tract. 8. David Hepburn: Double Superior Vena Cava, &c. 9. G. D. Hamilton: Weigert's Hæmatoxylin Copper Stain for Nerve Fibre, &c. 10. W. Hunter: Intra-peritoneal Blood Transfusion and the Fate of Absorbed Blood. 11. Sir W. Turner: Racial Characters of the Human Skeleton. 12. Prof. Humphry: Remarks on the Conditions, Habits, &c., of Centenarians. 13. R. Cory: Effects of Vaccination and subsequent Amputation of Supernumerary Fingers. 14. W. Menzies: Two Cases of Single Kidney. 15. D. Hepburn: Variations in Human Nerve Arrangements. 16. J. Lamont: Nerve-supply of Musculus Sternalis. 17. Abbé's Apochromatic Micro-objectives, &c. A very good number.

Analytical Records.

LANOLINE (LIEBREICHT.)

(MANUFACTURED BY BENNO, JAFFÉ, AND DARMSTAEDTER, BERLIN, FOR BURROUGHS, WELLCOME, AND CO., LONDON.)

THIS extremely interesting substance is prepared from the *suint*, or grease of wool. Crude suint, as is well known, contains potash salts, whereas the purity of this preparation is shown by the fact that it yields only a very small trace of ash. It contains mainly insoluble fatty acids, the soluble acids determined by the ordinary saponification method only amounting to 0·4 per cent. Its specific gravity at 120° F. is 0·911, and its melting point 113° F. (corrected). But its most remarkable property is that of taking up by mere trituration a very large quantity of water. We found no difficulty in incorporating as much as 150 per cent. of water, and it is said that even larger quantities may be introduced. It is sold in two forms, anhydrous and ordinary, the latter containing, according to our analysis, 20·74 per cent. of water. It is this power of mixing with water that suggested its use as an absorbent, for which it seems admirably adapted, as experience shows that the skin which has exuded it can as readily take it up. We regard it as an article of great promise, and shall look with interest for further records of its use.

DISINFECTANT AND DEODORISING CANDLES.

(THE DEE OIL COMPANY, SALTNEY, CHESHIRE.)

These candles are intended for use in the sick room, and generally in places where the air is of doubtful purity. They contain a real antiseptic, which can be separated by boiling in water or by careful sublimation. They burn with a fragrant odour, and seem well adapted for their purpose.

OLEUM DEELINÆ.

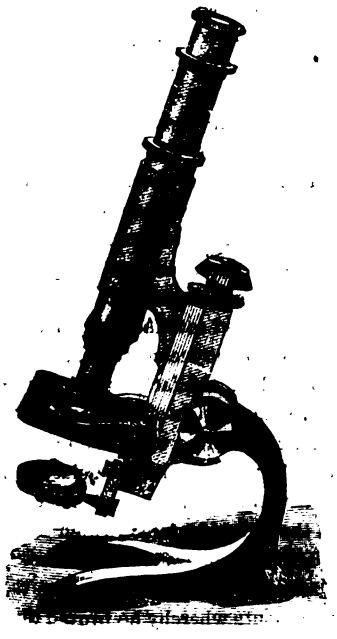
(THE DEE OIL COMPANY, SALTNEY, CHESHIRE.)

This is a mineral oil preparation intended for use in ringworm, eczema, scurvy, and other skin diseases. It is strongly fluorescent, has no taste or smell, does not give off vapour at 212° F., leaves no residue after burning, and is not acted on by sodium. Its purity is therefore evident.

SELLERS' HYPNOTIC TINCTURE.

(JOHN SELLERS & CO., FARRINGDON-STREET.)

The manufacturers state that this tincture, of which the dose is from half to one fluid drachm, is compounded of chloral, bromides, hyoscyamus, lupuline, cannabis indicus, and other drugs. Our analysis confirms this account, and we are the more disposed to praise the preparation because no attempt is made to conceal its composition.



WATER FAMINE IN LANCASHIRE.—Notwithstanding the heavy showers which fell a week ago, the inhabitants of Langho, near Blackburn, are suffering from a water famine. All water used has to be taken from Clitheroe by rail in milk cans. This is served out by the station-master, who allows a bucketful to each family. There is not a drop of water in the district except what can be obtained in this way.

New Inventions.

PILLISCHER'S NEW "KOSMOS" MICROSCOPE.

THE annexed woodcut illustrates a new student's histological microscope, recently made and brought out by Mr. Pillischer, of New Bond-street. A well-arranged optical body and stage, with a revolving diaphragm, is supported upon a solid bronze base or foot, which is at once original and most convenient, enabling the worker when using the stand to manipulate with the greatest ease. The fine adjustment is perfectly steady and sensitive, and will admit of the highest immersion objectives being used. The optical parts consist of one eye-piece and two objectives, a 1 in. and ⅓ in., of excellent defining and penetrating power, giving amplifications from 30 to 330 diameters. In its simplest and cheapest form—viz., the stand, one eye-piece, 1 in. and ⅓ in. objectives, and a well-made mahogany cabinet with lock, key, and handle—this microscope costs £5; but the stand is so constructed that any additional objectives or apparatus, such as Abbé's or achromatic condenser, polarising and other apparatus may be fitted to it. The maker claims for this instrument both mechanical and optical excellence to a degree which has hitherto not been attempted in cheap microscopes of this class. We can recommend the microscope as a good and cheap one, well suited to students' work.

KANGAROO TENDONS.

To the Editors of THE LANCET.

SIRS,—With your kind permission I would like to draw attention to a few rather important circumstances respecting the selection, treatment, and preparation of kangaroo tendons which are intended to be used surgically. Having read in THE LANCET at different times the opinions of several operators who have used them, I wish now to refer more particularly to the defects pointed out in your reports of the meetings of the Royal Medical and Chirurgical Society and the Clinical Society of London, in THE LANCET, vol. i. 1885, p. 286, and in vol. ii. 1886, p. 819, in which the following statements occur—viz., that tendon ligatures "had broken on more than one occasion"; that they "were sometimes slippery"; and that the knots tied in them "are apt to slip." My own experience is so directly opposite that I cannot help believing that the behaviour referred to was due to an imperfect condition of the tendons employed, and that they were either unsound or had been too much softened before being used. To ensure satisfactory results all tendons must be examined to ascertain that they are quite sound, because they are frequently injured by a hasty and careless removal from the animal's tail, a task requiring some little time and trouble, but not unfrequently performed by the rough hands of a boatman, who will, if not properly instructed, pull them out by main force, and by this heroic method they are seldom obtained of the proper length and strength, for they either break off short or they are frayed at their edges, or split longitudinally, and I have seen many such which had been sold for surgical purposes. A moment's careful scrutiny of the tendon ligature by the surgeon himself is therefore necessary before trusting to it in the deligation of an important vessel. It should be about eighteen inches in length; if less than fourteen it had better be rejected at once; it should also be of the same calibre, and the same width from end to end. Its surface and edges should be even and without flaw, quite free from frayed, broken, or hanging fibres, and without any splitting or longitudinal separation of its substance. The soundness, or otherwise, is at once apparent by holding the tendon out at length between the eye and the light. Who, may I ask, would employ a silk or a gut ligature in which one or more of the strands were notched or broken? In consequence of its natural wavy and irregularly interlaced structure, a tendon is greatly weakened by a very short longitudinal split in its substance. I have always been careful to point out that a split or damaged tendon would easily break. *Apropos* to splitting, there is an article in Heath's "Surgical Dictionary" on Kangaroo Tendons, which seems to me to be rather misleading, for the writer states that "when fresh the tendons may be split up to any thickness required." *Cui bono?* But with seeming inconsistency, the same writer advises, a few lines further on, the rejection of those tendons which show any "longitudinal split." Another surgeon mentions a case, reported in one of the numbers of THE LANCET already referred to, in which he used a "slightly flattened" tendon. If this flattening was made by pressure, as one must presume it was, it is apparent that the process materially weakened the fibre of the ligature. As regards the slippery surface that has sometimes been spoken of in London, it also is probably caused by the preceding treatment to which the tendons have been subjected, and I fear that I may possibly be responsible, though unwittingly so, for some of this treatment. At all events, I desire to point out an error which occurs in a short paper of mine in the Medico-Chirurgical Transactions, in which it is stated (vol. lxv., p. 73) that tendons can be preserved "in 5 per cent. carbolic oil." This should have been 1 to 5 carbolic oil. I regret that this mistake escaped unnoticed by me till a few weeks ago, when some tendons that had been preserved in 5 per cent. carbolic oil were brought to me for examination by a friend, who had followed the directions in the paper just referred to. They were decidedly soft, rather slippery, and altogether different from other tendons which had been preserved in 1 to 5 carbolic oil. This may account for the "slippery nature of the material used," which is complained of in one of the reports. My recommendations, however, when first introducing tendon ligatures—as recorded in the *Australian Medical Journal*, Dec., 1877, and on all other occasions, with the one unfortunate exception—have been that they should be preserved in carbolic oil, precisely in the manner directed by Professor Lister in the preparation of catgut ligatures. And in this way all those I have ever used, or seen used, have been preserved. And there can be no doubt that they improve and become denser by keeping for many months or years in this solution; in fact, they become rather too hard for immediate use, without some previous softening. From recent experiments it appears that the best way of removing the hardness is by immersion for a few minutes (say at the commencement of the operation) in a warm solution of carbolic acid and water, 1 to 40, at a temperature of about 120°, which makes them pliable, yet not slippery. This is better than soaking for a long time in a cold watery solution; such a soaking for twenty-four hours is apt to make them sodden.

A final word about the length, if not trespassing too far on your valuable space. It is hardly possible to tie a tight and efficient knot on a vessel with a short ligature, especially when the operator's hands are wet; therefore it is all the more important to insist that the tendons should be over fourteen inches long, in order to afford a good firm hold, besides the fact that to obtain a tendon at its full length necessitates care in its removal from the tail.

I am, Sirs, yours obediently,

T. M. GIRDLESTONE, F.R.C.S. Eng.,

THE LANCET.

LONDON: SATURDAY, AUGUST 27, 1887.

THE Bradshawe Lectures, which are delivered annually at the two Royal Colleges, have been productive of much that is valuable and interesting. The date at which the delivery is fixed at the College of Physicians differs from that of the College of Surgeons; but although strictly in accordance with the foundation, it is rather an unfortunate time for the gathering of a large audience. There is another difference besides the time of delivery which has become marked between the customs of the two Colleges. At the College of Surgeons the office of lecturer has been hitherto bestowed upon one of the senior Fellows or past presidents; at the College of Physicians the president has selected alternately a Fellow from the provinces and the metropolis, and has sought rather to encourage the junior Fellows by inviting them to undertake the office. Hence, we look to the occasion at the one institution for the ripened wisdom of experience and age, and at the other for the ardent investigations of workers in the field of medicine, in their endeavours to open up new paths and proffer new explanations of phenomena. This is strikingly the case with the lecture delivered last week before the College of Physicians. It was the product of a young physician who has brought to bear upon the explanation of a not uncommon pathological condition facts and experiments which illustrate well the bearings of the science of physiology upon practical medicine. Dr. SAMUEL WEST has already identified his name with the subject of pneumothorax, and in his lecture he succeeded in demonstrating how many and varied are the problems involved in this apparently simple condition, besides introducing to notice matter which is wholly new and highly suggestive. It may therefore be well to note some of the more salient features of the lecture, which appeared in full in our columns last week.

Limiting in the main his remarks to the occurrence of pneumothorax in the apparently healthy, Dr. WEST at first alluded to the experiments and observations of Dr. CHAMPNEYS, the correctness of which he has himself verified. From these observations it has been clearly shown that although the lung may be ruptured by violent expiratory efforts, the air rarely finds its way into the pleural cavity, but, burrowing beneath the pleura, enters the mediastinal, and thence the subcutaneous tissues. Subcutaneous emphysema is then more readily produced than pneumothorax; there is less resistance to the passage of air into the lax connective tissue than between the pleural layers, so that, as Dr. WEST subsequently stated, the occurrence of such emphysema is almost a safeguard against the graver issue of pneumothorax; for it was experimentally found that a force equivalent to eight or nine inches of mercury, far and away above the greatest expiratory effort, was needed to produce pneumothorax in the healthy lung. It follows, then, that in every case where this condition arises—as it mostly does in the "apparently healthy"—without any unusual strain or effort, the lung must be markedly weak. This inference is strictly in accord with pathological fact. Pneumothorax may occur in the very earliest as in the latest stages of phthisis, before the appearance of any physical signs, just as at the close of a well-marked case with numerous cavities. All that is needed is a minute sub-pleural softening focus, which may involve the pleura and admit air into its cavity. Nor is recovery from such a form of pneumothorax impossible; indeed, from the cases recorded by Dr. JOHNSON, Dr. WEST, and others of late, it not infrequently ends in this way. But, at any rate, no one can say now that pneumothorax can arise spontaneously in an individual whose lungs are perfectly sound.

A second highly interesting point in the history of pneumothorax was dealt with by Dr. WEST, whose experiments have decidedly thrown a new light upon one of the paradoxes of pathology. That the pleura may be laid open by an external wound, or the lung injured from within, as by rib fracture, without air being admitted into the pleural sac, has long been a puzzle to clinical observers. No explanation hitherto afforded can be deemed satisfactory. Pleural adhesions, although common, are by no means so widespread in area or so universal as to explain the fact, and the alternative hypothesis of a rapid reabsorption of the escaped air is even less tenable. When air gains free entrance into the pleural sac the lung collapses by virtue of its own elasticity, which is reckoned as equivalent to 7 mm. of mercury, Dr. WEST has shown that the cohesive force which keeps two layers of a healthy serous membrane in contact is much greater than this; and we commend to notice the ingenious and accurate experiments whereby he proved that, even when an aperture is made in the outer layer of membrane, no air will find its way between the layers unless a force equivalent to at least 12·5 mm. of mercury be employed to separate the two layers. The "law of cohesion" between two closely applied surfaces of the physical condition of serous membrane is one of considerable importance in animal physics, and is, as Dr. WEST showed, equally applicable to the peritoneum and to joint surfaces as it is to the lungs. The outcome of this doctrine is, then, that pneumothorax cannot be initiated without the intervention of a degree of force sufficient to overcome this cohesion, unless the pleura be already altered from the healthy state, to which, of course, this statement only applies. That force is supplied by expiration, and once it has effected the detachment of the two pleural layers, the elasticity of the lung completes the process, until the whole sac is filled with air.

The third point which received ample illustration at the hands of the Bradshawe lecturer was that of intra-pleural pressure in pneumothorax. It was shown that, whereas the expiratory pressure is always positive, and sometimes raised to a considerable degree, inspiratory pressure cannot exceed that of the atmosphere unless some other condition, as fluid effusion, is present. The value of this observation is obvious; and the interesting question of respiratory oscillation, or the difference between the inspiratory and expiratory pressures as influenced by the condition of the opening into the lung and the presence of fluid, received abundant illustration. The clinical value of the manometer could not be better exemplified; and it would

Digitized by Google

add largely to the value of our records were it customary to employ this instrument in connexion with the aspirator in every case of thoracentesis. The results of these variations in pressure are seen in the displacement of the heart, which was shown by Dr. WEST to be a bodily displacement, and not a merely rotatory movement. For these and further facts the lecture itself must be referred to. But there is still another question that was dwelt on by Dr. WEST which merits a few words; that is, the mechanism whereby in cases of recovery from pneumothorax the lung re-expands. Fluid may take the place of the air, and the recovery be effected by the natural forces of absorption alone or aided by paracentesis, the respiratory movements assisting powerfully to this end. It is different in those somewhat rare cases where no fluid effusion occurs, for then the absorption of the air from the pleural sac must take place with a power strong enough to overcome the pulmonary elasticity. There is no doubt of the interchange of gases contained in the pleural cavity; but it is at present an insoluble problem how all the residual gas is got rid of. Dr. WEST proposed an explanation, but admitted that it would hardly be considered final. It shows, however, that he is fully alive to all the difficulties of the question, and it forms not the least interesting topic in a lecture which was throughout lucid and instructive.

THE cry is not unfrequently raised that practice by quacks should be prohibited by law. Those who think that stringent legislative interference would prove successful would do well to listen to what is being said in countries where quackery is, nominally at least, illegal. Dr. AUGAGNEUR has recently contributed some articles on Freedom in the Practice of Medicine to a French provincial medical journal which he edits, in which he first reviews shortly the history of French medical legislation and its consequences, and then proposes a change in the direction of perfect freedom.

Under the old monarchy, medical practice was a monopoly enjoyed by bodies such as the Paris Faculty and the College of Surgeons of St. Côme, which were tolerably jealous of their privileges; but in districts far removed from Paris, sorcerers, bone-setters, &c., had it pretty much their own way. The pride and exclusiveness of the Paris Faculty received a severe but not altogether an undeserved check at the revolution by the suppression of all privileges hitherto enjoyed by medical bodies, and the establishment of entire freedom in the practice of medicine. In consequence of the complaints made by medical men restrictions were after a time again imposed, the chief argument in favour of this, which is attributed to FOURCROY, being that it was necessary to protect people who were too ignorant to discriminate between an educated medical man and a boastful charlatan. "The intention," says Dr. AUGAGNEUR, "was excellent, but look at the result a century after the restrictions were reimposed!—a century too, which has seen the development of railways and compulsory education." This law is a failure, not because the intelligence of the public generally has rendered it unnecessary, but because it is absolutely inefficient. Quackery is to be found everywhere under all kinds of forms—bone-setters, [illegible] and now, as the latest products of a scientific age, electricians, magnetisers, and hypnotisers, who drive a more prosperous trade than even the charlatans of a more primitive character. The press, the glorious instrument of popular education, disseminates daily the most barefaced falsehoods about quack medicines of all kinds, and the pharmacists who do not abuse their position by selling such articles are unfortunately in a small minority. Again, persons who possess diplomas—midwives, *officiers de santé*, and even Doctors of Medicine—act in collusion with quacks by allowing their names to be advertised in connexion with secret remedies. "Not long since one of these diploma'd medicine vendors, whose advertisements were to be seen on the last page of numbers of newspapers, secured the patronage of a Parisian professor, who defended his doings before the Academy of Medicine." "What is to be done? There are only two methods—legislation of Draconian severity, which public opinion would never stand, or complete freedom." Either the police must proceed against every person who practises without a diploma, and advertisements of medicine vendors must be entirely prohibited in general papers, or complete freedom to practise and advertise must be conceded. In this connexion it must be remembered that many valuable remedies have been discovered by lay persons, and that M. PASTEUR himself is not a medical man. There is another matter, too: the State now is obliged to recognise officially many practitioners whose acquirements are far from what they should be. Examiners do not like to go on rejecting a man *ad infinitum*, and so, after various attempts, men who are by no means really competent are passed, otherwise their means of earning a livelihood would be taken away from them. If practice were free, such men could study for as long or as short a time as suited them, and could begin practice whenever they liked. They would not of course be able to call themselves "Doctor," but would have to content themselves with the designation of "Medecin" (medical practitioner), which would mean nothing more than engineer or photographer does. There would, however, Dr. AUGAGNEUR thinks, be this great advantage about the system of free practice: the degree of Doctor might be reserved for those who were thoroughly competent, which, according to him, is by no means the case under the present *régime*. His plan is to do away with the lower diploma of *officier de santé*; to punish usurpation of the title of Doctor of Medicine by a heavy fine and two months' imprisonment, no extenuating circumstances being recognised; and of course to allow none but Doctors of Medicine to hold public medical appointments or to be called as experts in courts of justice. He would make all persons, whether with or without diplomas, responsible for their treatment; the Minister, acting under the advice of a medical committee, to prosecute in cases of malpraxis, without waiting for a complaint to be made by the patient. Under a few years of this system Dr. AUGAGNEUR prophesies that quackery would have nearly disappeared, and with it the *officiers de santé* and the majority of incompetent Doctors of Medicine. This would appear to be a very sanguine view of the result of legislation. As far as the freedom of practice goes, we have it in this country in all its glory, and actions for malpraxis are probably quite as common as they would be if they were entrusted to a Government department. We have, besides, a law against

Digitized by Google

assuming medical titles, which, though sometimes evaded, is by no means a dead letter; yet quackery is rife, and is apparently not at all on the decrease. We have also—what the French have not—the unqualified assistant question; and although recent events may possibly have the effect of checking some of the more gross abuses connected with the employment of unqualified men, it is highly improbable that any legislation which the public would tolerate would put an entire stop to unqualified practice. Even the Germans and Russians, who are accustomed to more of the iron-handed style of legislation than we are, are unable to put down quackery. Things are no better in America, where medical legislation is very lax, so that it is to be feared that Dr. AUGAGNEUR'S panacea would prove as ineffectual as other systems.

THE rapid progress of chemistry, particularly of that part of it known as "organic chemistry," outstrips all those who either have no time or no inclination for hard scientific reading. Every few years our text-books are transmogrified; old and familiar names give place to new; and as for the formulæ, many of us are compelled with reluctance to give them up in despair. Omitting the changes due to the revision of atomic weights, which are definite and have become familiar to most, we are confronted with an almost interminable series of variations in the formulæ for well-known bodies, and are tempted to ask, with some vexation, whether acetic acid is $C_2H_4O_2$, or $HC_2H_3O_2$, or $H_2O.C_4H_6O_3$, or C_2H_3OOH, or $CH_3.COOH$. Is there any meaning in such changes? Do they record real discoveries of facts, or merely the latest fads of theorists? Could chemists do without them? Would it be simpler or more complex if they were discarded? Are they of practical use in interpreting present facts and guiding new research? And, above all, have they any appearance of finality about them, or must we look for an endless series of analogous changes? Answers to these and to similar questions cannot be supplied in a few lines or even a few pages, but an interesting and satisfactory attempt is made in a recent number of our contemporary, *Nature*. The author of the article entitled Constitutional Formulæ and the Progress of Organic Chemistry (*Nature*, Aug. 18th, 1887) points out in a very clear manner how the atomic hypothesis led to symbols, formulæ, and equations, and how the later discoveries of isomerism and the physical phenomena incidental to chemical composition and chemical change have led to new hypotheses. Of the value of these hypotheses there can be no doubt, for they have fulfilled in a remarkable manner the great condition of all good working theories, in that they have not only proved equal to the explanation of many, if not all, of the problems which research has presented, but have endowed the experimenter with something of the prophetic skill which is required for new discoveries. The so-called constitutional formulæ of modern chemistry show, at any rate, one possible mode in which the ultimate atoms may be grouped in each individual compound, and suggest not only other groupings of those atoms that would belong to isomeric varieties of the same substance, but also probable modes of synthesis and of decomposition. The defects of the formulæ to which we are at present restricted are self-evident, and are universally admitted. They represent atoms at rest and on a plane, both of which conditions are most improbable. As we know more of molecular and atomic dynamics, we may learn to modify or even to change them, but as far as they go, and in the present state of our knowledge, they are invaluable, and could not be discarded without grave injury to scientific progress. To conclude, in the words of the article which has led to these remarks, "The constitutional formula is not an ultimate expression of the whole truth as regards molecular structure. But it is certainly a very convenient symbolical expression of certain aspects of the truth. We all hope that it may one day be superseded by some higher and more complete generalisation; but it will be absorbed and assimilated, not rejected and contradicted, by that generalisation. *Non omnis moriatur.*"

PERHAPS the diseases of the various parts of the nervous system which may come on during the course of the different "fevers" is one of those subjects on which the present and immediate future are destined to throw considerable light. The discoveries of recent years have been made not only in the clinical, but also in the anatomical sphere, and some observers have happily combined the clinical with the anatomical methods, much to the advancement of true pathological knowledge. The ball may be said to have been re-started by the remarkable discovery of PITRES and VAILLARD that phthisis might be attended with peripheral neuritis, which would explain the presence of certain marked nervous symptoms; and perhaps still more by the circumstance that the same observers detected a similar affection of the peripheral nerves in typhoid fever. These newly recognised facts have widened very considerably the horizon of our clinical and pathological knowledge. The facts, however, that alcohol is a cause of phthisis, and that alcohol is at times freely given in typhoid fever, should be remembered, since alcohol is a proven cause of peripheral neuritis. We now perceive that various fevers may give rise to nervous symptoms and lesions by acting either on the brain, spinal cord, or nerves, and that their deleterious action on these structures may partake of the nature of almost any known anatomical lesion.

Let us examine for a moment the various kinds of symptoms and lesions that have been described as occurring during the course of continued fever. Many observers have noted alterations in the spinal and muscular functions, but readers of THE LANCET will have been made acquainted with their remarkable prevalence by the contributions to our columns last year and this by Dr. ANGEL MONEY, who affords support to the suggestion made by Dr. HUGHLINGS JACKSON that the knee jerk may be found of some utility in the differential diagnosis of typhoid fever and meningitis. For many years past it has been known that various groups of muscles either in the arm or leg may be paralysed during typhoid fever, and even the cranial motor nerves have been known to become diseased—indeed actual signs of neuritis have been observed after death; but still the recent investigations of PITRES and VEILLARD have shown that a neuritis may involve several peripheral nerves without there being such gross changes as have hitherto gone to establish the existence of neuritis. The suggestion has been made that any fever, if sufficiently long continued, may set up peripheral neuritis; and the facts which have

Digitized by Google

been ascertained would appear to give some support to the theory. Of other paralyses that have been observed in or after typhoid fever mention may be made of laryngeal paralysis and palsy of the soft palate, which have also been complicated by paralysis of the act of accommodation for near vision, thereby suggesting the well-known paralysis which follows diphtheria. Further careful observation will be necessary before these rare palsies after typhoid fever can be said to be of an altogether satisfactorily proved occurrence. The white matter and the grey matter of the cord have been known to be the seat of lesions during and after typhoid fever, and with all the symptoms corresponding thereto and fully explicable thereby. Many years ago, in 1861, LEUDET described a case of typhoid fever in which the legs became first paralysed towards the end of the third week of the malady, and afterwards the paralysis spread upwards till the arms and chest became involved, and the patient succumbed from asphyxia within a week of the development of the first paralytic symptoms. Spasmodic and atrophic forms of spinal paralysis have also been observed, and lesions of corresponding parts of the gray matter and white columns have been discovered at necropsies, sometimes made at long intervals from the onset of the paralysis. Although the disease was measles, still the fact may be cited as of great interest and of recent discovery, for DR. THOMAS BARLOW found evidence of hæmorrhagic myelitis in the spinal cord, and this developed at the same time that the rash came out in the skin and the bronchial tubes were the seat of acute catarrh; and Dr. BARLOW suggested that the spinal cord might be regarded as being specially involved with a sort of measles-rash in his case. Although the occurrence of such marked lesions in the cord is unusual, still we must admit the possibility of a slighter vascular disturbance of the cord as a more general concomitant of severe measles. If we inquire what effect typhoid fever may have on the brain, we shall perceive that the cerebral lesions hitherto observed have been neither few nor limited. Perturbations of mind, disorders of memory, melancholia, general paralysis, hemiplegia, and aphasia, have been often witnessed, but the difficulty is to know to what precise lesion these effects are to be attributed in the different cases. Many theories suggest themselves, but the facts on which they can be based are few in number, and not of frequent attestation. Mere prolonged pyrexia or mere toxæmia may conceivably spoil the protoplasm of the nervous centres; or these processes may damage the texture of the vessels which supply the nervous tissues. Again, as POPOFF has shown, congregations of leucocytes and colonies of micrococci may collect in scattered foci about the cortex of the brain, and perhaps in other parts of the central nervous system, in acute fevers; or, as Dr. CHARLTON BASTIAN discovered some time ago, minute embolisms or thromboses of capillary vessels may be the cause of some of the nervous symptoms and lesions in typhoid states. Besides minute changes, such gross pathological occurrences as thrombosis and embolism of large vessels, together with actual formation of aneurysms and hæmorrhages, have been considered as the cause of equally marked symptoms occurring actually during or soon after the continued

Annotations.

"Ne quid nimis."

SCARLET FEVER IN LONDON.

THE increase of scarlet fever, upon which we commented in our issue of last week, still continues, and the most recent return shows that there are 724 persons suffering from this disease in the hospitals of the Metropolitan Asylums Board. No one part of the metropolis is specially invaded, but the disease is scattered over the whole area, and is therefore in all probability due to personal contagion. London suffers from scarlet fever in epidemic proportions every few years, and it may be assumed that its prevalence is in great part dependent upon the accumulation of susceptible persons who have grown up since the previous epidemic. Thus, while the annual average number of deaths in London in the years 1876-85 is 2140, during the years 1884-86 the number of deaths has been respectively 1430, 722, and 688, and the numbers have not exceeded 2114 since the year 1880. The deaths undoubtedly bear some proportion to the number of cases, and hence there must be many children in London who have, until the present epidemic, escaped this malady. Of 91 persons admitted into the hospitals of the Metropolitan Asylums Board during the week ending August 19th, as many as 77 were under ten years of age, and 38 under five years of age. When consideration is had for the fact that there is a tendency to keep very young children at home, these figures teach an important lesson, and show that the present epidemic is in great part dependent upon the immunity enjoyed by young children in preceding years. But apart from this circumstance, there are other conditions, not yet understood, which influence the dissemination of scarlet fever. Every health officer knows that there are years when children suffering from the disease can be treated at home with much less risk to other members of their families than during other years, and this difference in the behaviour of scarlet fever deserves further investigation. We have now, fortunately, a department of the State which concerns itself with inquiry into the causes of disease, and we would suggest that it might usefully employ in the examination of the conditions to which we have referred those health officers who have special aptitude for detailed work of this nature.

A SWEDISH SURGEON ON EXTIRPATION OF THE FALLOPIAN TUBES.

DR. F. WESTERMARK of Stockholm, who has now performed extirpation of the Fallopian tube ten times, contributes a paper on the subject in the report of the Sabbatsberg Hospital. After dealing with the history he goes on to discuss the indications for the operation. First of all, as to tubal pregnancy, the best period for operating is before rupture has occurred; Veit having operated eight times, and Gottschalk twice, with entire success, in this stage. As a rule, however, women seldom come under observation till after rupture has taken place. When this has occurred, he considers the operation indicated if the internal hæmorrhage and the collapse produced are not sufficiently severe to place the patient from the first *in extremis*. Other methods which have been suggested are, he believes, uncertain, and even more dangerous than extirpation. Of thirty of these cases with which he is acquainted, a fatal result only occurred in two. Respecting hydro- and pyo-salpingitis, he points out that a very characteristic pain occurs in the pelvis, which is always more marked a little before each menstrual period, and which sometimes becomes spasmodic in character and almost unbearable in amount. These pains, he thinks, are due to spasmodic contractions

Digitized by Google

of the tubes caused by increased turgescence of the tubal tumour. Continuous pain, on the other hand, is, he believes, a sign of perimetritis, which is nearly always present, and which he by no means considers an indication for the operation; he even seeks to subdue the perimetritis before operating. In uncomplicated cases of salpingitis the diagnosis is simple, but where ovarian abscess or cysts coexist with it the diagnosis is sometimes impossible without a preliminary laparotomy. In cases where the diagnosis is rendered difficult by perimetritic effusion of large amount, he recommends a long course of absorbent treatment before operating. The chronic forms of salpingitis ought invariably to be operated on, and likewise some of the acute forms—e.g., gonorrhœal. He had a case of this kind which he operated on about a month after its commencement, and was able to trace in the preparation distinct groups of gonococcus. In the catarrhal form he seems less disposed to recommend early operation. Of nine operations for salpingitis only one proved fatal; and here the disease was tubercular, and was followed by tubercular peritonitis. From statistics of other operators he deduces that the mortality from 498 extirpations has been forty-one, or 8·2 per cent. Regarding the question of operating for new growths, Dr. Westermark agrees with the views of other surgeons who have written on the subject.

FARTHING DINNERS FOR SCHOOL CHILDREN.

SOME months ago we noticed with cordial approval the efforts which had been made in Birmingham to supply cheap and nutritious dinners to poor children attending elementary schools. Some further papers descriptive of the movement are now in our hands, and we commend them to all who are interested in philanthropic work, and, indeed, to all who have the good of their country at heart. The new papers are a second edition, revised and enlarged, of a pamphlet by Mr. George Herbert Sargant of Birmingham, entitled "Farthing Dinners," a report for the season 1886-87 on Birmingham halfpenny and farthing dinners, and a report on two conferences held in Manchester under the auspices of the Vegetarian Society in the spring of this year, on the economy of our food supply, and upon cheap dinners for school children. Mr. Sargant, to whom the success of the Birmingham experiment is in a great measure due, has done a further and more general service in publishing his experience in a somewhat extended form. His pamphlet can now be obtained from Messrs. Simpkin, Marshall, and Co., for twopence. In it he has given minute directions for the selection of suitable food material, cooking apparatus, and kitchen and table appliances, and tables of the price of each. For the daily supply of 400 or 500 children the initial expenses for cooking and serving, including tables, linen, &c., is stated to be £25 13*s*. This is the maximum, and in many cases it may be greatly reduced. In the earlier days of cheap dinners it was thought a triumph to supply a meal sufficient for an average child for a penny. It was then successfully reduced to a halfpenny; but, alas! even this was too expensive a luxury for many of the poor little things. So Mr. Sargant set to work again, and by dint of close study and careful purchase succeeded in preparing wholesome and nutritious dinners, the absolute cost of which was only one farthing each. It seems incredible, but we are assured that this is the actual cost of the rations daily issued to the poorest children in Birmingham. No less than 12,000 dinners a week are now sold or given away in the town, and although the dinners are scanty for strong and well-fed children, they are said to be ample for the ill-fed and sickly, and it is for the latter that the boon is chiefly needed. The dinner consists of half a pint of soup and a slice of bread and jam, and the main reason of its amazing cheapness is that lentils, split peas, Indian meal and barley, with carrots and onions, are used, to the exclusion of meat. Of the nutritive value of such food there can be no doubt, and as to the quantity, we presume that two meals may be had for a halfpenny. Mr. Sargant gives a most encouraging account of the effect of the simple meal upon the intellectual progress as well as on the health of the children; but for that, as well as for an able statement of the arguments for and against free dinners for Board School children, we must refer our readers to the interesting pages of his pamphlet.

A RESERVOIR OF THAMES WATER NEAR A HOSPITAL.

THAMES WATER in an unfiltered state may, perhaps, be good enough for forge work and for extinguishing fires, but when a large volume of it is pumped into a reservoir situated directly under the windows of a large hospital and allowed to lie stagnant for some time there at this season of the year, the danger to the inmates is considerable. These remarks are prompted by the horrible stench which has been emanating for some time past from the circular reservoir at the top of Woolwich Common, close to the Herbert Hospital. This reservoir (which, it may be remarked, though pretty carefully railed round, is a somewhat favourite spot for suicides) is connected with the Woolwich Dockyard, now no longer used for its original purpose, but employed as a store of warlike material. The reservoir is filled with Thames water, which at Woolwich is never particularly savoury, and at this season of the year is frequently very offensive. The dockyard and the residential quarters in it are supplied with wholesome water by the Kent Waterworks Company from deep wells at Deptford, Orpington, and St. Mary Cray; but for certain purposes of a manufacturing nature, and as a reserve in case of fire, Thames water is laid on from the old reservoir, which is on high ground.

TRAUMATIC HEMI-EPILEPSY CURED BY OPERATION.

DR. HOUZÉ, physician to the St. Jean Hospital in Brussels, gives in *La Clinique* an account of a case of hemi-epilepsy due to a blow from a quoit on the left parietal bone, where trephining was performed with ultimate success. The patient was admitted into the medical wards in February, 1886, having then suffered for three years from frequent and violent fits, which always commenced on the right side of the body, and then passed over to affect the left side. There was, besides, motor aphasia of articulation and ataxic dysphagia, due to spasm of the tongue and hemiparesis; also fibrillar contractions, movements of extension and flexion, and ascending and descending auras. These phenomena had first shown themselves in the leg then in the arm, and finally in the neighbourhood of the facial and hypoglossal nerves. By means of a seton applied to the nape of the neck and very large doses of iodide of potassium, the aphasia, agraphia, and the hemispasm of the tongue, together with the brachio-facial twitchings, completely disappeared. From September, 1886, to January 25th, 1887, there were only four fits, the twitchings in the intervals being confined to the right leg. It was then determined to give the patient the benefit of an operation, and he was transferred into the surgical wards, where M. Thiriar trephined above the situation of the fissure of Rolando. After the second attempt a splinter of bone was discovered adhering to the surface of the endocranium, and the dura mater was observed to be peculiarly white at that spot owing probably to a proliferation of connective tissue due to irritation of the splinter. The wound healed perfectly. From Jan. 25th, the day of the operation, to Feb. 11th th symptoms had diminished considerably, the vaso-motor

Digitized by Google

troubles having ceased on the fourth day. From Feb. 15th, however, the symptoms reappeared one after another, and on the 23rd there was an epileptic fit, which commenced, as the former attacks had done, on the right side, and rapidly affected the left. The next few days there were from three to eight attacks per diem. The seton was reapplied and large doses of iodide given. This treatment again produced a great effect, there being no fit from Feb. 28th to May 4th, the other symptoms having also almost disappeared by that date. On June 7th the patient complained of severe pain in the right thigh, and of frontal headache and want of appetite. There was, however, no tenderness over the scalp or the courses of the nerves, but the temperature was raised. The next day there were twitchings of the muscles, and the day following that a herpetiform eruption on the right leg. After that there were no manifestations of the former condition beyond some slight twitchings of the right leg up to July 10th. When the patient left the hospital he still continued to take iodide in the form of the sodium salt. M. Houzé has good cause to congratulate himself on the accuracy of his diagnosis and his correct localisation of the source of irritation.

"OVERWORK" IN THE COMMONS.

THE conditions of service in the House of Commons are rapidly becoming too hard for any but the most robust of men. Unless a change be quickly inaugurated, there will be no hope of retaining in the public service of the country those busy men who are, by habit and experience, best qualified to make the laws in the administration of which, as magistrates, lawyers, or men of commerce, they have so large an interest. Country gentlemen, barristers, manufacturers, and merchants cannot possibly labour both day and night without respite, even for the good of the commonwealth. What makes the exhausting character of work in the lower House of Parliament especially provoking is its utter needlessness. It is purely wasteful, not merely of strength but of time, to protract the sittings of the Commons beyond reasonable hours. As a matter of fact, if the wretched system of "talkee talkee" were not supported by both parties there would be no occasion to sit an hour after midnight. Eight hours four days each week for six months in the year would amply suffice. Making the most liberal allowance for the advance of intelligence and the destructive effects of progress, it cannot be that our statutes and laws generally are so quickly rendered obsolete that the large amount of time legitimately available for legislative purposes, without turning the whole of the night into day, is inadequate. We cannot help thinking that a great awakening and reconstructive change in our method must be in the near future, and will be hastened by the discovery that many valued lives are being ruthlessly worn out by the worry and work which the present manner of legislating involves.

THE PETRIFACTION OF ANIMAL BODIES.

A WELL-KNOWN Padua chemist and physician, Dr. G. B. Mastedaglia, who died more than forty years ago, discovered a method of petrifying animal bodies, and gave the University museum several specimens of his work. This method he kept secret, but he wrote it all out and left the directions in a sealed packet to his legitimate heirs by will. These legitimate heirs, however, were not to be found; and, in spite of every effort to discover them, they remained until recently unknown, and the sealed packet remained therefore unopened. Lately, however, they have been found, and have been besieged by applications for the secret, large sums being offered to them for it. They have, however, it seems, decided not to part with it—at present at least.

THE CARE OF PAUPER CHILDREN.

PUBLIC attention has recently been directed to the care of poor children who are removed from the charge of their parents by the Boards of Guardians, and much evidence has been forthcoming that constant attention must be given by the Local Government Board to ensure that careless administration shall not inflict injury upon them. Within a few weeks the Central Board has had to make inquiry into allegations of neglect of children boarded out by the St. Pancras guardians, of cruelty to the children of the Holborn Union in the schools at Mitcham, and of accusations of inhuman treatment of children suffering from ophthalmia in the schools at Norwood belonging to the Lambeth Union. The first was shown to be but too well founded, and some effort was made to reflect on a system which undoubtedly confers benefits on many young children. The chief fault of our Poor-law system is that the young brought up in large institutions fail to develop any individuality or to become fitted for future occupation in the life that is before them, or in the large world in which they must subsequently earn their livelihood. To some extent this difficulty has been met by placing these children in the families of poor persons, where they are subject to, at any rate, some of the conditions with which they will be surrounded in their after life. The gain by this method of treatment has been sufficiently distinct, but it is obvious much local supervision is required to ensure that they are maintained under circumstances which are advantageous to them personally; a break-down in one locality must not be regarded as a reason for condemning the whole system, but it points to the need for a better supervision than has heretofore existed. Concerning the cruelty to children at Mitcham, this has been shown to exist through the misconduct of officers of the local authority, and the Local Government Board have acted wisely in insisting upon the removal from office of those who were chiefly to blame. The accusations of improper treatment of children at Norwood appear to have arisen from a want of understanding on the part of some members of the Board of Guardians that the methods usually adopted for the cure of granular lids were not more severe than the nature of the cases warranted. Dr. Bridges, who, on behalf of the Local Government Board, investigated the matter, was able to assure the guardians that this malady would yield only to the treatment which had been carried out, and his opinion will be supported by all who have experience of this disease. There appears to have been some exaggeration as to the sufferings of the children, but it may be assumed that much discomfort would be experienced, and that those who had no knowledge of the benefits of the treatment might take exception to its adoption; but the guardians will doubtless be satisfied now that a full explanation has been received from so trustworthy a source as Dr. Bridges.

"MASSAGE AND ELECTRICAL TREATMENT."

WE have received from medical men numerous circulars forwarded to them by a Limited Company, with many indications that in their opinion electricity is not to be used in this wholesale fashion in medicine. Accompanying the circular is a lithographed letter from Mr. J. F. Leeson, L.R.C.P. Lond. and L.R.C.S. Ed., who is described in the Company's circular as having had "a long and varied experience in hydro-therapeutics, electricity, massage, and medical rubbing." One would think this specialty enough to credit to any single medical man in a very business-like circular. But it no sooner ends the description of the staff for electrical operations, under Mr. Leeson, than it goes on to say: "Dr. Leeson will also undertake all difficult cases of hernia requiring special attention," and on the

Digitized by Google

opposite page is a warm eulogium of a certain truss. We have only to mention such advertisements to indicate our disapproval of them and that of the profession. We cannot but regret that a member of the profession should lend his name for use in such business-like circulars. We feel sure that a little reflection will satisfy him that this is neither the way to commend electricity to the profession nor to lead to the acquisition of a knowledge of its refined use in fit cases, which Mr. Leeson will admit to be essential.

THE CAUSE OF INFANTILE DIARRHŒA.

THERE is no problem in public sanitation or in pathology more interesting than the radical and essential cause of infantile diarrhœa. The mortality from this disease is very great, and the illness occasioned by it, even where not fatal, is still greater. We are glad to have been able to lay before our readers in THE LANCET of last week a suggestive paper by Dr. Tomkins of Leicester, a town scarcely more notorious for its absurd opposition to vaccination than for the prevalence and fatality of infantile diarrhœa. We commend the paper to all medical officers of health and to all physicians who have special opportunities of studying this disease. The drift of Dr. Tomkins's careful investigations is to show, as we are all prepared to learn, that the disease depends on micro-organisms. He does not pretend to have defined or identified them; he is, indeed, excessively careful to show that his observations are still very incomplete. But of course they go far to show that in the organs of those children dying of the disease, especially in the ileum and the kidneys, micro-organisms were obtainable from which abundant and rapid cultivations could be obtained, the nutrient material used being gelatine. The bacilli so obtained, or rather the gelatine in which they were cultivated, developed a markedly alkaline reaction, and even in highly diluted quantities a powerfully offensive odour. It is equally important to note that Dr. Tomkins has been able to obtain the same organisms developing the same odour in the air of Leicester, but not with the same success in all parts of the town. In those parts of the town where the disease most prevails the organisms numbered from 2000 to upwards of 5000 or 6000 per cubic metre, whereas in the healthier and more open districts they varied from 60 or 80 to 800 or 900 per cubic metre. He uses every opportunity to ascertain the pathological lesions in such cases, but has not found them coarse or striking to the naked eye, consisting mainly of inflammatory changes extending through the intestinal canal, and most severe in the ileum. Small ulcers, too, were present in most cases, but they were not localised as in typhoid fever. It is satisfactory to think that Leicester has a health officer so bent on elucidating a problem which he has special opportunities of studying.

THE SABBATSBERG HOSPITAL, STOCKHOLM.

FROM the recently issued report of the work of the Sabbatsberg Hospital, Stockholm, for the year 1886, we learn that 3169 patients were treated there during that period, with a mortality of 257, or 8·11 per cent. On Jan. 1st, 1887, 263 patients remained in hospital. The total cost of each patient per diem was 1*s.* 7*d.*, the food being about 4¾*d.*, and the medicine about 1½*d.* Since 1884 the hospital has been illuminated by the electric light, there being 228 incandescent lamps. The cost per lamp per hour was 0·15*d.*, including interest and sinking-fund charges. In order to enable the hospital to be cleaned and thoroughly aired during the summer, a pair of temporary wards have been obtained, made of thin wooden boards, each to accommodate thirteen beds. The cost of these was about £150. The number of major operations was 785 in the surgical, and 125 in the gynæcological department.

THE DIGESTION OF CARBO-HYDRATES.

THE paper of Ellenberger and Hofmeister, recently published in *Biedermann's Centralblatt*, contains a summary of their long-continued researches on this subject. They have experimented upon the horse, and their conclusions are by no means identical with those that have hitherto been received. An abstract, by Mr. J. Fletcher, of this important paper appears in the current number of the Journal of the Chemical Society; and it is so lucid and concise that we reproduce it almost *in extenso*.

"The action of saliva in the process of mastication is shown to be more mechanical than chemical. The quantity of saliva used depends on the dryness and roughness of the food rather than its contents in starch; and the authors think that the chemical activity of saliva owes much to spores, which, floating in the atmosphere, mix with the food and assist in the fermentation process. A digestive action of the mixed food takes place in the stomach when the acidity due to hydrochloric or lactic acid does not exceed 0·03 to 0·04 per cent. The left section of the stomach of the horse does not secrete a gastric juice; this is the function of the right portion. The pure gastic juice of the horse contains lactic, fatty, and amylaceous ferments—the latter in small quantities. Cellulose is not digested in the stomach of the horse, but muscle, fat, gelatine, and flesh generally are easily digested, bone and elastic tissues more slowly. Pepsin operates actively only when acids are present, about 2 per cent. of lactic acid or 0·2 per cent. of hydrochloric acid being necessary. The activity of pepsin does not increase in proportion to its quantity after reaching a certain point, but it rather becomes injurious. The acid which appears first in the digestive process is lactic acid, and later hydrochloric; at the time of greatest activity lactic acid is present in the upper and lower extremities of the digestive tract, hydrochloric acid being found in the intervening part. The digestion of starch in the stomach of the horse lasts for about two hours; that of albuminous matter takes place later, and occupies three or four hours after the eating of the food. The drinking of water immediately after food does not appear to hinder digestion. The secretions of the intestinal canal unite in themselves all the properties of the gastric juice, and can act as a substitute for it, and are particularly energetic in the decomposition of fats. The duration of the digestive process in the horse is long, lasting almost three days. A very active lactic fermentation of sugar takes place in the stomach and intestines, but the authors do not say that all the sugar which is lost in the course of passage is lost in that way; it is more probably reabsorbed."

THE CASE OF LIPSKI.

IN our editorial remarks on the case of Lipski, in our last issue, we drew attention to the difficulties that surrounded the investigation as gleaned from our contemporaries, and from the meagre reports that appeared at the time of the trial. The reader will find, on referring to our annotation, that we were anxious that the evidence in all its bearings should be thoroughly weighed. It was not our purpose to hamper the executive, but to assist, although in an indirect manner, to unravel the tangled skein of facts proved, reported, and reputed. There can be no doubt that Mr. Matthews was in possession of the knowledge of circumstances of the tragedy much more fully and perfectly than most suspected; and now that all is over, we offer to him our tribute of respect and admiration for the exceeding forbearance and energy he displayed in what must have been to him a very trying ordeal. He has tempered justice with mercy, and held the scales until one side kicked the beam. Mr. Matthews is to be congratulated on not having made an ignoble surrender to the mob advocacy of Lipski with which he was beset. The case will long remain a memorable one,

Digitized by Google

as having been the occasion of a vigorous, long-sustained, and very general plea for clemency to the convict. This we cannot say we altogether regret, for it has shown that several points of medico-legal interest were, on cursory examination, open to other interpretations than the one arrived at by the jury at the Old Bailey. But, quite apart from Lipski's confession, we were content that the Home Secretary, with the concurrence of Mr. Justice Stephen, would arrive at a righteous conclusion. The days of Scroggs and Jeffreys are past; nor is there reason to dread that Home Secretaries will fly in the face of reason and justice, and recklessly give the *fiat* for a fellow creature's death. The most that their responsible duties demand at the hands of the public and our own profession is kindly assistance. Attempts at coercion must end—as they deserve to do—in shame and confusion.

ICHTHYOSIS HYSTRIX NIGRICANS.

IT is not necessary to suppose that the trophic influences of nerves are alone active in the causation of any disease which happens to follow the course of well-known nerves. On the posterior part of each thigh of a child six years old Dr. Butruille observed a long band bounded by parallel lines, and composed of horny growths of a pronounced grey or nearly black colour, and of irregular aspect and hard consistence. There were a few scattered nodules of the same kind; but it was clear that the tract of the disease corresponded with the general direction of the great sciatic nerve. On the right leg the direction of the ichthyotic disease was along the path of the internal popliteal nerve, whilst on the left it followed the course of the external popliteal and anterior tibial nerves as far as its splitting on the dorsal aspect of the foot. A similar distribution was found in the front of the elbow and forearm, as though the fish-like skin was taking its direction from the median nerve. In addition to the overgrowth of the horny layers of the epidermis, there were redness and chronic inflammation of the underlying skin; but with this exception there were no other lesions, and careful examination failed to detect any patches of anæsthesia, analgesia, or hyperæsthesia. The disease was first noticed a few months after birth, in the form of two reddened tracts on the posterior aspect of the thighs, which appeared to have been formed of lines composed of projecting red papules. Such a case, like others that have been recorded hitherto, may be explained by supposing that the disease ran in a general direction with well-known nerves as the result of a mere coincidence, though the association is a curious one; or it is possible that a slight influence coming from the nerves may have decided the direction which the disease took, without in any way supposing that the nervous trophic influence was the chief cause of the ichthyosis.

THE EDUCATION OF VAN CHILDREN.

THE strength of a chain is the strength of its weakest link. If the general truth of this axiom be admitted, then the effective value of that chain which represents our national system of education can hardly be tested at any point so well as in its application to the state of our nomadic population. Mr. George Smith of Coalville has repeatedly roused public opinion to action on behalf of the neglected children of van-dwellers. This perseverance, in spite of the great passive resistance of inertia which belongs to a task at first sight so thankless as the effort to supervise and to train this wandering race by any regular process, is worthy of all praise. He, and many more who favour his disinterested purpose, will certainly view with satisfaction the probable realisation of their hopes as far as that can be assured by the passing of the Bill relating to this subject. This measure, which is framed on the same lines as its predecessor, the Canal Boats Act, besides dealing with the question of education, will also necessarily provide for the registration and inspection of vans and the carrying out of sanitary requirements. Van-dwellers are on the whole a healthy people, thanks to the fact that their lives are passed so much in the open air. Their moving cabins, however, cannot, under the ordinary conditions of domestic life, be regarded as either wholesome or convenient. Only the out-of-door daily life of their occupants counteracts their essential tendency to become at any time nests of contagia acquired in the towns through which they have to pass. In view of this risk and of the prevailing neglect of childhood to which we have alluded, the Bill now under the consideration of Parliament is one which can but appeal to the judgment of everyone who understands that healthy growth of mind and body among the members of every class is the foundation of national prosperity.

SANITARY NEGLIGENCE IN AUSTRIA.

AUSTRIA is credited by *The Times* correspondent at Vienna with taking little interest in sanitary matters, and an amusing story is told in an evening contemporary of a high official who expressed disapproval of a reduced death-rate because it interfered with the public revenue from succession duty. Indeed, it is broadly stated that the upper classes are satisfied with the erection of luxurious buildings, irrespective of their influence upon health. Some difficulty arises through the unwillingness of provincial authorities to carry out the laws enacted by the Imperial Diet, and in so simple a matter as the examination of cattle and meat the local authorities in the Tyrol have attempted to evade their duties, and have appealed against the decision of the Diet on this subject to the Court, which has to decide disputes between the central government and provincial authorities. It is hoped the International Hygienic Congress, which will be held in Vienna next month, will create a warmer interest in public health questions.

THE PREVENTION OF LEPROSY BY SEGREGATION.

IN anticipation of the forthcoming quinquennial report on Leprosy in Norway for 1881-5, the Director of the Norse Leper Department, Dr. Hansen, has forwarded Brigade Surgeon H. V. Carter, M.D., a short preliminary summary of the latest results of the segregation of lepers as carried out by the Norwegian Government, which Dr. Carter, ever keenly alive to the bearing of these facts on India, has communicated to the Bombay Government Gazette (June 30th, 1887). The total number of lepers officially registered, had between the years 1856 and 1880 inclusive, diminished from 2863 to 1582, and of the latter 617 were lodged in the Government Asylum and 965 were living in their own homes. The diminution in the home-dwelling lepers is still going on, so that in 1885 there were only 354 men and 291 women, making 645 in all, or a decrease of 31·24 per cent. in the last five years, or in the course of twenty-nine years a tolerably regular progressive diminution from 2628 to 645, or 75 per cent. Were it not for the circumstance that the asylum population has of late years been reduced, from economic reasons, to about 500, the hope would have been realised that by the year 1885 50 per cent. or one-half of the entire leper community would be isolated. Further good results should follow from the enactment by the Norse Parliament in June, 1885, that the sanitary officials in the country districts be authorised to inform the leper subject that, as a condition of being allowed to dwell at home, he must take satisfactory measures against risking the infection of other people. Amongst other interesting points we notice that Dr. Hansen has probably succeeded in inoculating rabbits with *perfectly fresh* leprous

Digitized by Google

material, but these experiments require confirmation, He finds the bacilli in the anæsthetic form of disease, and always in wandering cells amidst the epidermic scales surrounding the true leprous ulcer of the nodular form. As bearing on the hereditary nature of leprosy, Dr. Beaven Rake relates an interesting, though, as he admits, in no way conclusive, case in his Report on the Trinidad Leper Asylum for the year 1886. A leper woman was admitted with an apparently healthy child eighteen months old. The child was sent to an orphanage, and about one year later developed leprosy.

THE INFLUENCE OF SANITARY MEASURES.

IN a report on the sanitary state of Hull, Dr. John W. Mason, medical officer of health, points to the influence of the provision of a proper system of sewers in lowering the mortality from certain diseases. During the years 1881–85, the western district of the borough was provided with a continuous instead of an intermittent outfall for sewerage. Phthisis and rheumatism will, it is believed, be materially alleviated by this measure, which permanently lowers the level of the subsoil water, and, by preventing the backing of sewage up subsidiary drains, deals even with the temporary choking of the subsoil with wetness. But as regards the zymotic diseases a change is already in progress which is worth recording, without necessarily attributing the whole of it to this one measure of sanitary progress. In 1881 the zymotic death-rate for the western district of Kingston-upon-Hull was 5·6 per 1000 living; and since that date it has almost steadily diminished, until in 1885 it was only 0·8 per 1000; the general death-rate from all causes meanwhile falling from 2·41 to 18·4. During that period 58,546 feet of drains were laid and 2394 houses connected with the sewers in the district in question.

A FUTURE FOR INDIAN WOMEN.

FOR many years there have not been wanting signs that the mind of the people of India is gradually freeing itself from the restraints which custom, inspired by superstition and social prejudice, has cast about it. The advantages acquired through a co-partnership with ourselves in modern methods of education, in facilities for European travel, and in such practical conveniences as the railway and the telegraph, have not lacked appreciation by many of our Oriental fellow-subjects. Chief amongst these advantages we would place the fundamental benefit conferred by a liberal and carefully directed education. Whatever the progress it has made hitherto, whatever temporary drawbacks or failures may have marked the periods of oscillation natural to advance in that as in any other direction, there can be no reasonable doubt as to the true position of this primary gain in the estimation of all who concern themselves to gauge its possible influence if allowed to act without restraint. It must of necessity in India, as elsewhere, be largely instrumental in reforming many objectionable practices which continue to disfigure personal conduct and social usage. It will undoubtedly do much, for example, to disabuse the native mind of its ingrained attachment to the practice of compulsory betrothal and marriage, with its too frequent sequel of child widowhood. A more cruel or disgraceful folly than this latter could hardly be credited to human nature. The pitiless lot assigned by Indian custom to the child widow was known in this country long before the case of Rukmabai attracted attention. Her case, hard though it is, is not to be compared with the misery of many of these children, who, bereft of friendship, scant of food, deprived of the very decencies of life, drag out an outcast existence, begun almost in infancy, simply because a husband, whom, perhaps, they have never seen, has died before them. Well may we feel a sense of shame that British law has been successfully invoked in justification of a forced marriage arranged in childhood, and of reproach that it is as yet powerless to lighten the sorrows of those poor children. Some effort in this direction, we trust, is not beyond the scope of early legislative reform. In the meantime we cannot but offer our cordial adhesion to a scheme in which it is suggested that an asylum be established for the reception of any of these outcast children who may be permitted to enter it. It has been proposed that there they should be instructed in the duties of attendance on the sick, with a view to their formation into a native nursing staff. A body of young native women thus trained is one of the crying needs of India at this time. Their youth, acquaintance with eastern character and custom, their familiarity with the language of their country, as well as with its diet and the changes of its climate, combine to fit them in a peculiar degree for waiting upon the native population, without reference to our fellow-countrymen, during illness. It is much to be desired by all classes of the people of India that a staff of this kind should be created, and we therefore commend the scheme to their most earnest consideration, as well as to that of the Government.

CHOLERA INTELLIGENCE.

THE returns as to cholera in Italy are not sufficiently definite to enable us to record the total number of cases and deaths. The main incidence of the disease is still upon the island of Sicily. But there is sufficiently accurate information to make it pretty clear that there has been some spread in the mainland. From Resina the news is more encouraging. Suspicious cases are said to have occurred in the provinces of Benevento and Avellino, and in Rome itself; and as regards Naples, it is distinctly asserted that the cases there have been somewhat numerous, and that a considerable number of cases had been admitted into the cholera hospital. A few cases are also reported from the province of Capua. From Sicily itself the news is mainly concerned with two provinces, and during the week ending the 22nd inst. there were in the province of Catania 152 deaths, and in that of Palermo 98 deaths, the outbreak clinging with considerable tenacity to both provinces. In Malta cholera is also maintained, fresh attacks and deaths being recorded every day. During the seven days August 16th to 22nd those newly attacked were 66 in number and the deaths amounted to 39. Owing to the maintained prevalence of cholera in Italy, it is generally apprehended that the Local Government Board are about to renew the order which expired some time back, and which prohibited the importation into this country of rags from that kingdom.

RECENT PHYSICAL DETERMINATIONS.

MANY determinations of the densities of the liquids which so short a time back were only known as permanent gases have been made, but until very lately it has been impossible to compare them on account of the various conditions under which the experiments were made. But very recently Dr. Olszewski, to whose elaborate researches on this subject we are already greatly indebted, has succeeded in overcoming the difficulties of comparison. Taking advantage of the very low temperature produced by the evaporation of liquid ethylene, he succeeded in finding not only the boiling point of the liquefied gases at the normal atmospheric pressure, or very near to it, but also its specific gravity at this pressure. It is of course of particular importance to know the specific gravity at the boiling point, because this fixes the specific volume. Working in this way, Olszewski found for the three important liquids, methane, oxygen, and nitrogen, the following numbers:—Methane: pressure, 736 mm.; boiling point, −164° C.; density, 0·415.

Digitized by Google

Oxygen: pressure, 742·1 mm.; boiling point, −181·4°; density, 1·124. Nitrogen: pressure, 742·1 mm.; boiling point, −194·4°; density, 0·885. Scarcely inferior to the above research in interest is that of M. Amagat on the influence of pressure on the point of maximum density of water. It is well known that this liquid, remarkable in so many respects, occupies a less volume at 4° C. than at higher or lower temperatures. Hence the expansion of water is irregular, and is unlike that of any other liquid. But we now learn that this peculiarity only exists under ordinary pressures. When the pressure is increased the point of maximum density falls, and at 200 atmospheres it is almost identical with zero; with greater pressure the irregularity of expansion lessens, and at 3000 atmospheres it disappears and water behaves like any other liquid.

THE BRITISH DENTAL ASSOCIATION.

THE annual meeting of the British Dental Association was held last week in the hall of the Faculty of Physicians and Surgeons, Glasgow. The popularity of this institution is growing, as was shown by the statement of the secretary that there was an increased number of members, and there was a goodly number present, although the meeting lacked some well-known names, perhaps owing to the approaching International Congress at Washington. Sir Edwin Saunders, Mr. Smith Turner (the newly-elected President of the Association), Mr. Felix Weiss, Mr. Morton Smale, and many others took part in the proceedings, Mr. Brownlie (Glasgow) being in the chair. Amongst the papers of most general interest was one by Dr. George Cunningham on "The Dental Aspect of Public Health," which followed much the same lines as his and Mr. Fisher's papers last year, to which we referred at length at the time. At the conclusion of his paper the following resolution was agreed to:—

"That this meeting is of opinion (1) that wherever the State provides medical services, dental services should be provided for as an essential part of such medical provision; (2) that, having regard to the great importance of securing competent attention to the teeth of the army and navy, the representative board should consider the advisability of urging the Government to make suitable provisions to that end; and (3) that, considering the compulsory attention to the teeth of school children would be a national gain, the representative board should be empowered to further the matter in any way they deem most fit."

Mr. Lloyd Williams contributed a paper on "Antiseptics in Dental Surgery," which showed that the success in the treatment of dental diseases was largely due to their use, and that they were of great importance in preventing infection, septic or specific, by instruments. Messrs. Walter Campbell and Jas. Cumming also read papers.

EXCESSIVE SECRETION OF GASTRIC JUICE.

DR. WILKENS, of Stockholm, reports a curious case of periodic hyper-secretion of gastric juice, for which no cause or explanation is forthcoming. The patient was a musician of the age of thirty-six, who had lived in different countries, but had never suffered from digestive troubles till three years and a half previously, when he was seized with vomiting and pain in the abdomen, rendering him incapable of eating or drinking while the attack lasted. Similar attacks recurred at intervals of ten or twelve days, lasting from twenty-seven to thirty-five hours, and during them the patient was forced to keep his bed. It was found that he lost from two to three and a half kilogrammes in each attack; in the intervals he suffered from excessive hunger. The vomit presented all the characters of gastric juice. The quantity passed during each attack was about two pounds and a half; the acidity was 0·12 per cent. The only explanation that Dr. Wilkens can suggest is that this excessive flow depends on some affection of the secretory nerves of the stomach.

THE SURPLUS OF THE WOMEN'S JUBILEE OFFERING.

THERE was wisdom in the selection of the purpose to which the surplus of the Women's Jubilee Offering is to be appropriated. Women's work among the sick is an enterprise of great interest and value, and there is obviously a special fitness in the determination to utilise the money collected from women by women in honour of the Jubilee for the promotion of their benevolent mission. Only one better proposal could have been entertained, and that was the distribution of the fund in aid of the hospitals. This being set aside, possibly under the impression that it would be difficult to allocate the money in that direction effectively without merging it in a fund which it would not so much strengthen as complicate, the decision at which Her Majesty has arrived is one which must at once command the respect and sympathy of her subjects, and especially of those by whom the fund was contributed. That being so, we have only to express the hope that the committee commanded to advise the Queen will do so in a spirit of large-minded sagacity and benevolence worthy of the undertaking in which they are engaged. The nursing of women and girls by women, which we understand to be the particular branch of nursing specially eliciting Her Majesty's interest, is an enterprise that urgently needs help, and the timely assistance afforded by this Royal direction of an almost national fund towards its resources cannot fail to prove of invaluable service, if only it be judiciously applied.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Hartmann of Naumburg.—Dr. F. J. Hairon, Emeritus Professor in the University of Louvain, formerly President of the Belgian Royal Academy of Medicine, and ex-Director of the Ophthalmic Institute of the Belgian Army.

CUTANEOUS CALCULUS.

CALCULI in the skin are not of common occurrence; at the same time they can hardly be said to possess much importance except as articles of curiosity. One of fair size was recently removed from the skin of the left cheek of a woman, aged sixty-five, by M. Dubois Havenith. It does not seem possible for the stone to have been extracted from the parotid duct, for the disease was mistaken at first for a cancroid, on account of its hardness, and from its being covered with a crust; but there was no enlargement of the corresponding lymphatic glands; and a dental fistula, though a possible explanation, was negatived by careful examination. The stone was irregular, mammillated, weighed about five grains English, had the volume of about a quarter of a cubic centimetre, and was composed of phosphate and oxalate of lime and cholesterin.

SANITATION IN CALCUTTA.

IN the second quarterly report on the health of the town of Calcutta Dr. Simpson discloses a most discreditable state of affairs on the part of those who are responsible for the health interests of the community. Dr. Simpson points out that cholera and typhoid fever are always sufficiently present to call for systematic inspection of premises and their surroundings, but that this work cannot be carried out without

Digitized by Google

an agency. He then states that the sanitary inspectors who, he had hoped, were the officials by whom the work was to be performed, and who were the nucleus of the sanitary department which he desired to see established in the city, have been dismissed. A real sanitary department in Calcutta has heretofore only existed in name, and now it appears that the sanitary organisation for carrying out inspections, which the most insignificant village in England possesses, is lacking for this great eastern capital, with its terrible death-rate from preventable causes. Had there been no inspection of the special surroundings of the dairy and other premises which led to the discovery that in the case of the *Ardenclutha* those who were attacked with cholera had used the implicated milk, that outbreak, like others in Calcutta, would probably have gone to swell the list of cholera cases due to so-called climatic causes.

THE EPIDEMIC OF ENTERIC FEVER AT MOUNTAIN ASH.

THE severe outbreak of enteric fever at Mountain Ash is said to be extending and to call for unceasing labour on the part of the medical practitioners of the district. Up to the end of last week 140 attacks had occurred, and a period has now arrived when the deaths have commenced, five fatal attacks being recorded. Happily, there is reason to believe that the cause of the extension of the epidemic has been discovered. The outbreak has been almost exclusively confined to a suburb of Mountain Ash known as Miskin, and there it has been found that the choking of a branch sewer had led to a large block in the sewerage system, with the result of forcing back upon the houses the fetid emanations arising from the decomposing sewage. This block has been dealt with; and we may hope that the sanitary circumstances of the place are such that, the initial cause once removed, the further spread of the disease will be checked.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Professor Hertwig will commence his lectures as Second Professor of Anatomy in October. Dr. Schmaltz has been appointed to the second Professorship of Anatomy in the Veterinary School.

Jena.—Dr. F. Semon has qualified as *docent* in Anatomy.

Kiel.—It is reported that a Hygienic Institute and a Professorship of Hygiene are to be established.

THE Vienna Academy of Sciences have elected Dr. Leopold Pfaundler, Professor of Physics at Innsbruck, and Dr. Hubert Seitgeb, Professor of Botany at Gratz, Members; Dr. Karl Toldt, Professor of Anatomy at Vienna, Dr. Sigmund von Wroblewsky, Professor of Physics at Cracow, Dr. Ernest Fleischl von Marxon, Professor of Physiology in Vienna, Home Corresponding Members; and Professor H. E. Beyrich of Berlin, Foreign Corresponding Member.

DR. BILLROTH, our readers will be glad to learn, is steadily regaining health and energy at St. Gilgen, by the pleasant waters of the Wolfgang-See. He hopes to resume his prælections with the reopening of the winter session.

THE Crown Prince of Germany has written to Professor Virchow, announcing a continued improvement, and thanking the renowned pathologist for his investigations into the character of his Imperial Highness's malady.

DR. EDMUND NEUSSER, assistant in Professor Bamberger's Medical Clinic in Vienna, has been appointed Body Physician to Prince Ferdinand of Bulgaria.

THE INTERNATIONAL CONGRESS OF HYGIENE.

VIENNA, famous historically as a seat of Congress, will four weeks hence give hospitality to the greatest numerically as well as philanthropically that has yet assembled within her walls. To the invitations issued by the Organising Committee of the International Congress of Hygiene 1320 affirmative replies have been received. The ordinary members will be numerous enough to suggest the thought that the gathering is as much an ethnographic as a hygienic one. Austria contributes 788, Hungary 182, Germany 85, France 63, Belgium and Italy 24 each, Russia 19, Switzerland 13, England 12, Holland 9, Denmark 8, Roumania 5, North America 5, Spain and Egypt 3 each, South America 2, and Portugal, Bulgaria, and Turkey 1 each. The official representation is also considerable. The common Ministries of Vienna and Buda-Pest depute 15 delegates; the Austrian Government 12, the Hungarian 18, the French 10, the Belgian and Swiss 4 each; the German kingdom, the Bavarian, the Saxon, the Spanish, the Netherlands, and the Egyptian, 2 each; the Italian, the Danish, the Portuguese, and the Norwegian kingdoms, 1 each; Brunswick, Hamburg, Lübeck, Bremen, Roumania, Servia, Persia, and the Argentine Republic also 1 each. The proceedings will relegate to the second line all purely controversial themes of hygienic science, and deal mainly with the thoroughly practical questions of human well-being. Of the twenty books and *brochures* distributed by the Hygienic Section among the members of the Congress, some of them ranging from 100 to 150 pages (the Demographic Section has limited itself to two *brochures* of a few pages each), the subjects dealt with are—Water in all its aspects as a Necessary of Life, including Drainage, and the preservation of Rivers from Pollution; the Utilisation of Human Refuse; the Adulteration of Food; Alcoholism; the Hygiene of Schools, of Seafaring Vessels, and Factories; the erection of Isolation Hospitals; the Protection of Animals from Epidemic Disease by Inoculation; the Etiology and Prophylaxis of Cholera, considered with reference to the recent European visitations—the whole field, in short, of sanitary science in its rigidly practical bearings. The special sections, as well as the general meetings, will assemble in the new university buildings. Within the same walls has been brought together, chiefly through donations, a splendid hygienic and demographic library, which, after the close of the Congress, will become the property partly of the University Institute for Hygiene, partly of the Central Statistical Commission. In connexion with the library there is also a magnificent assortment of plans and graphic representations of what may be called the *matériel* of sanitary and demographic science. The residue of the money subscribed for the Congress will be devoted to a foundation for the promotion of "fabriks-hygiene"—to remain as a monument of the Congress long after its immediate programme has been fulfilled. Demography, we may mention, will be represented at the Congress for the last time on this occasion, its votaries having made special arrangements with the newly organised Statistical Institute for enrolment among its members.

The organising committee, as already remarked, has now issued in printed form the opening address, dealing with the twenty-two subjects set down for discussion. These in themselves constitute a formidable volume, and will enable all the members of the Congress to obtain a complete insight of each subject that is to be debated. The greater number of papers are in German, but these, for the most part, are accompanied with summaries of the main argument written in French. After German, second in number are the discourses in French, and finally there are four papers in English. The first is a report on the Purification and Utilisation of Sewage, by Dr. E. Frankland of New Reigate; the second is a short Report on the Importation of Rags, by Professor Corfield; the third is an account of the Laws relating to Factories and Workshops, by Mr. F. Hayes-Whymper; and the fourth is a paper on International Regulations for preventing Epidemics, by Mr. Shirley F. Murphy. This latter may probably lead to a somewhat stormy debate, as it will be remembered that English ideas on quarantines were left in a minority of two at the last Congress, held three years ago at the Hague. Among the French papers, M. Durand-Claye's summing up of the Shone and Waring

Digitized by Google

systems of drainage is certain to elicit very warm contradictions. Indeed, we already hear of various speakers who are preparing for the fray; and it must be borne in mind that the debates open on September 26th, so there is not much time to be lost. The excursions and various entertainments all seem to have been organised on a very grand scale and with much method, and the number of adherents to the Congress being unprecedentedly large, everything indicates that this gathering will be more successful than any of its predecessors.

THE FROZEN MEAT SUPPLY.

THE enormous importance of everything which has a bearing upon the food supply of Great Britain gives a very special interest to much of the evidence which was tendered to Mr. Justice Stephen in the course of the long patent trial with which he brought his judicial labours to a close for the legal year now just ended. The subject matter of the patent in question is a refrigerating machine, and interesting as its theory may be as a branch of thermo-dynamics, it would have been little but a piece of laboratory apparatus but for one thing. It has been found applicable to the important purpose of bringing dead meat from America, Australia, and New Zealand in a perfectly sound condition. The trade is at present in its infancy. Ten years ago, although experiments had been made with a view to the importation of cargoes of dead meat, they had all met with very indifferent success. The trouble arose out of a very trifling circumstance. Air contains, as everybody knows, a certain proportion of water vapour. This is, indeed, rather a popular way of putting the fact. If atmospheric air be considered to be strictly a mechanical mixture of oxygen and nitrogen, then of course it does not always and necessarily contain water. But although oxygen and nitrogen are often spoken of as being the principal (and sometimes roughly as the only) ingredients of common air, this is hardly accurate. So long as oxygen and nitrogen were regarded by physicists as "permanent gases," radically different from condensable vapour, like steam or carbonic acid, it was natural to draw a line between the gaseous and vaporous constituents of the atmosphere. But that distinction holds no longer. The brilliant experiments of Andrews, of Cailletet, of Pictet and others have recently shown that the most volatile gases are only vapours at a temperature much above, or a pressure greatly below, saturation point, and in this view it is impossible any longer to deny to the omnipresent and beneficent water vapour which paints our sunsets and fertilises our fields its right to the position of a constituent of prime importance in the terrestrial atmosphere.

But prior to 1877 it almost seemed as if this subtle vapour would for ever shut Great Britain off from the greatest dead-meat markets of the world. The problem was to preserve the meat during a voyage lasting from two to five weeks, and involving, in the case of the southern hemisphere, the crossing of the equator. The solution was obvious—viz., to reduce the temperature of the chamber in which the meat was carried to a point that would arrest putrefaction. Other methods of antiseptic treatment had indeed been tried, but not only without success, they had never even offered a reasonable prospect of success. An antiseptic dressing may do no harm to living flesh, because the vital processes speedily eliminate foreign elements; but once lodged in the substance of dead animal tissue, the antiseptic dressing became itself a ground of offence, and one which no subsequent treatment could wholly or satisfactorily remove. Not so, however, the treatment by what may, perhaps, be termed antiseptic temperature. This demands no counteraction but the subsequent thaw, and leaves no ineradicable mischief behind it. This, then, was, as we say, the obvious solution, and for years was only obstructed by the difficulty of dealing in the refrigerator with the inevitable water vapour. Unlike the so-called "permanent gases," water vapour is always present in the atmosphere, under ordinary conditions, in such quantity as to be actually at its point of saturation. A slight increase of pressure or a slight fall of temperature suffices to precipitate some portion of this vapour. Hence the difficulty. The engine is required suddenly to accommodate in the liquid or the solid form what up to that moment has been present only as a gas; and it is not surprising, therefore, that many—most, indeed—of the engines that have been constructed for this purpose have been liable to clog through accumulations of ice and snow.

The deposition of water as a result of increased tension in water vapour, though theoretically correlative to the deposition through reduction of temperature, does not, indeed, give rise to any practical difficulty. Indeed, in practice it is somewhat in favour of the operation, for as a matter of experience great reduction of temperature is almost always accompanied by simultaneous reduction of pressure. Thus the one condition tends to promote evaporation, while the other is producing condensation. But it falls far short of effecting a complete compensation. Our readers will remember the beautiful experiment of Cailletet, alluded to above, in which hydrogen gas, after being subjected to an enormous pressure and to the refrigerating influence of freely evaporating carbonic acid, was allowed to stream through a cock into the open air. It might have been supposed *a priori* that the relaxation of pressure, which itself produced the cold, would have countervailed the condensing effect of the cold so produced. But it was not so. In the centre of his emergent jet of liberated gas little lumps of solid hydrogen formed and fell upon the floor. In the same way grains of ice form in the expanding water vapour when the reduction of pressure is considerable, and these grains of ice, accumulating in the working parts of the machine, have of course a strong tendency to block it up. How strong this tendency is may be collected from the evidence of one of the engineers, who told Mr. Justice Stephen that "cold air machines are frequently made to deliver 1,680,000 feet per day, and this would produce about 5 cwt. of snow equal to three cubic yards in twenty-four hours without taking into account evaporation from the meat, and this on the assumption that the air taken into the machine is already below freezing." It may well be supposed that the disposal of such a quantity of solid matter generated within the machine would in any case be a serious problem, but it is complicated by the circumstance that this mass of snow comes into existence precisely where it is most mischievous. In order to get the full refrigerating effect, it is necessary to make the air do work during its expansion, and consequently it must be expanded in a closed chamber, in a cylinder in fact. This accordingly is where the snow is formed, and the problem of its removal in the solid form must be faced if once the water vapour gains admission.

Stated thus, the difficulty conveys a hint as to how it may be evaded. All that is wanted in the expansion cylinder is the permanent gas. If the water vapour can be removed the whole difficulty is at an end. Completely to remove it is not practicable, is not desirable perhaps, for it is probable that the desiccating action of a truly anhydrous atmosphere would have a deteriorating effect upon the meat cargo. But by the simple expedient of cooling down the entering air, before admitting it to the expansion cylinder, to a temperature just above 32° F., and giving it time to deposit its condensed moisture in a liquid form, the practical difficulty has been overcome. The liquid water runs away under the mere action of gravity. The residual vapour, though still producing snow, produces so much less than if it had gone into the cylinder at an ordinary atmospheric temperature as to make all the difference between commercial failure and commercial success. Equipped with this contrivance, the merchant finds it as easy to make his way through the circumambient ocean of water vapour as to traverse the subjacent ocean of liquid water, and without risk or trouble to bring his inert cargo of perishable meat for a six weeks' voyage through the tropics. Already the boon of this great enlargement of his meat supply is being felt by the British consumer. Last year it seems that a million frozen carcases arrived in London from New Zealand and the River Plate. In April of the present year 131,000 carcases of frozen mutton were received. Thus a beginning has been made of what will probably in the end prove to be a most important departure in the department of our food supply.

ACCORDING to advices from Jamaica, brought by the Royal Mail Company's steamer *Orinoco*, small-pox has entirely disappeared from the island, but several ports of Cuba are declared to be infected.

THE MANCHESTER EXHIBITION.

THE Manchester Exhibition has proved a great success. The number of visitors has exceeded all anticipations, and at first their advent caused no slight confusion. Thus, the catering came altogether to grief, and there was not food enough to feed all the hungry sightseers. This, of course, was very soon rectified. It cannot, however, be said that all the people who thronged the door of the Exhibition came for the sole purpose of studying the exhibits. At Manchester, as at the South Kensington Exhibitions, there are many other attractions. The gardens are expansive and effectively illuminated, and there is the extra and exhilarating prospect of a ride on the switch-back railway, or a wild career down the toboggan slide. The play of the fountains at night, illuminated by coloured rays of electric light, the excellent bands without, the organ recitals within, the numerous cafés and refreshment bars, the quaint reproduction of an Old Manchester street, achieved in as elaborate a manner as the Old London street at South Kensington, and, above all, the most glorious, sunny, dry weather, have all contributed to render the Manchester Exhibition a success.

Technically viewing the exhibits, there is more to interest the chemist than the doctor, and the chemistry relates rather to industrial enterprise than to sanitary reform. Nevertheless, there are some points of special interest which deserve a few words of notice. For instance, Messrs, Leveson and Son, of London, Manchester, Leeds, and Liverpool, exhibit six invalids' carriages, carefully swung on bicycle wheels; and there are the patent royal Hansoms of Messrs. Forder and Co., of London and Wolverhampton; and the landau and broughams of Mr. J. C. Windover. Then, to go from large things to small, writing nibs and pens generally are of practical interest to a profession so often called upon to prescribe; under these circumstances, the firm of Joseph Gillott and Sons will be welcomed among the exhibitors, particularly as they show us every stage of the manufacturing process necessary to produce the pen, which Bulwer-Lytton has aptly described as "mightier than the sword." There are also our old acquaintances and useful servants, the Owl, the Waverley, and the Pickwick pens of Messrs. Macniven and Cameron; and by the side of these, the medical publications, the anatomical models, and preparations of J. Pentland Young (Edinburgh), the educational publications of Messrs. Cassell and Co., including popular and most useful science works, and the elaborate exhibits of the well-known Manchester publisher, John Heywood. It is, of course, to this latter firm that we are indebted for the very complete and well-organised catalogue of the Exhibition. In the Old Manchester street Mr. Heywood shows us how printing and bookbinding was done in the Caxton period. This quaint and living record of the past is not without its sanitary lesson. Both the men and women engaged in the printing and bookbinding trades were evidently dressed some 300 years ago in a manner far better suited to our climate. The dress was practical, simple, artistic, and of such stout woollen materials as could defy the damp and cold, or the sudden, unseasonable heat, of an English winter.

In the matter of furniture, also, there are many things of interest. Messrs. Neville Glegg, of Altrincham, have gone to the trouble of showing how an artisan's living room might be furnished to secure the greatest amount of health, comfort, and economy in a limited space. Messrs. J. Davenport and Co., on their side, have artistic and sanitary wall papers free from poisonous colouring matter.

Section 8, devoted to chemical and collateral industries, possesses, of course, the greatest number of objects that more particularly concern the profession. The chemical apparatus and scientific instruments of Messrs. James Woolley and Sons, and the laboratory tables of John Haywood, both of Manchester, are effectively and neatly arranged. The former firm has also elegant antiseptic preparations for nursery and toilet use. There is, indeed, a large assortment of disinfectants. MacDougall's carbolic and sulphurous disinfectants, Jeyes' sanitary compounds, the Hydrofluate sanitary soap powder, and a new antiseptic named "Saltifer."

In the same section there is a very large assortment of soaps. Price's Patent Candle Company have an excellent opaque coal-tar soap. When this soap is transparent it contains a certain portion of glycerine and alcohol; there is consequently so much less washing material. The coal-tar soap in question, however, has neither the one nor the other of these ingredients. It is made of tallow, like pure primrose soap, with an addition of 5 per cent. of coal-tar; it is not black, and need not be black. For those who desire glycerine this firm manufactures a pure solidified soap, which contains no less than 50 per cent. of glycerine, and it is this large quantity of glycerine that produces the transparency without any addition of alcohol. In many soaps the transparency is secured by the presence of sugar and alcohol alone. Price's Candle Company, for example, showed us some of their hard transparent soaps that contain no glycerine whatever. They have recently introduced a new method of removing glycerine from neutral fats by means of magnesium instead of lime, and this enables them to obtain a glycerine of a much purer character. Their soap, containing 50 per cent. of glycerine, must be regarded as a purely medical article, and is not meant for ordinary daily use. Where, however, glycerine is required, it would be difficult to find a combination giving so large a quantity in the form of soap.

Among the goods of other manufacturers, we noticed the hazel soap of Messrs. James Alexander and Co. of London; the health soap of the Health Soap Company, Liverpool, who also show their process of manufacture; the soaps and oils of Messrs. Senior and Brooks; the well-known sunlight soap of Messrs. Lever Brothers, with a complete model of their very large works; and the samphire soap of Messrs. J. C. and J. Field. Some white Windsor soap of Messrs. Joshua Margerison and Co. seemed very inexpensive, and being made with potash instead of soda is suitable for hard water. The Pedeline powder and soap, made by Mr. F. Round, chemist of Southport, was attracting considerable attention. Used for washing the feet and for powdering the inside of boots or socks, it is presented for the prevention of sore, tender, or unpleasant feet.

In the same section, we also noted that Mr. J. W. Lovibond of Salisbury exhibits a tintometer which, though meant for testing the density of dies and colouring material used in manufactories, would serve as a quick, ready means of applying the Nessler's test in the analysis of potable waters. Near at hand, Herr Franz Müller has some German chemical and physical apparatus; and there are several exhibits of non-poisonous paints, notably Freeman and Co.'s white-lead paint, which, however, only professes to be free from injurious smell. There were many exhibits of chemicals for bleaching, finishing, dyeing, and calico printing, which, according to their freedom from mineral and vegetable poisons, have a great effect on the health of workers in the factory and in the mills.

There is an entire group devoted to indiarubber and gutta percha, and here Messrs. David Moseley and Sons have waterproof garments that are necessarily most useful to those who are compelled to face all weathers when calling on their patients; and the Ancoats Vale Rubber Company show domestic and surgical indiarubber articles worthy of note. The exhibits of Owens College, Manchester, constitute a small historical, chemical museum of great retrospective interest; and it was a happy idea to include this collection in the Third Section. Close by, Messrs. Thomas Christy and Co., of London, have many raw and manufactured drugs and some specimens of the less known medical plants. They give great prominence to methods for inhaling.

With regard to sanitary matters, such as ventilation and drainage, we could not find anything remarkable. Even Messrs. Doulton and Co. were not up to their usual high level of excellence. The newest object they exhibited was a graphic drawing which facilitates the appreciation of their improvement in the Stamford drain-pipe joint. Nor is the Exhibition building itself satisfactorily drained, for we could discover no trace of the intercepting man-holes, and the inlet and outlet ventilation of the soil pipes so well shown by this firm at the London Health Exhibition. The closets of the Manchester Exhibition, we believe, drain straight into the sewers without any interception and without any ventilation of the soil pipes. At all events, though we made several inquiries as to this point, we could find no evidence of these most indispensable precautions. We ought also to enter a protest against the condition of the ornamental waters in the gardens. These were extremely dirty, and consequently lost much of their attractiveness to the eye.

Digitized by Google

In spite, however, of these drawbacks, the Exhibition as a whole, is well organised, and has, we repeat, proved a great success. The machinery in motion is naturally, for a town in Lancashire, the principal part of the Exhibition, unless we include the art gallery, where many of the *chef d'œuvres* of English art, painted during the last fifty years, will be found. There is also an Irish section that has elicited considerable praise. Finally, though the Exhibition is some distance from the centre of Manchester, it is easily reached both by tram and rail. We trust it may still remain open for some time, as it will amply repay a visit on the part of those who have not yet been able to avail themselves of the many excursions and opportunities afforded of inspecting this collective display of northern industry and progress.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Hull Urban District.—Dr. Mason reports the general death-rate for Hull during 1886 to have been 18·6 per 1000, and the zymotic rate 2 per 1000. Both these rates exhibit a substantial diminution on the average rate for previous years, and the items which go to make up the latter are indicated in a useful but simple form by a diagram which discriminates between deaths from general and zymotic causes. Diarrhœa was by far the most fatal of the zymotic diseases, the rate from that disease alone reaching 1·37 per 1000—a higher rate than any since 1882. The deaths under one year of age are also high, amounting to 164 per 1000 registered births. Dealing with diarrhœa, Dr. Mason points out how favourable summer heat is to fermentative changes, which lower the vitality of the young and the aged, thus rendering them more liable to succumb to this disease, which he regards as being doubtless dependent upon the reception and propagation of some micro-organisms in the system. The hospitals for infectious disease continue to do service, the new sanatorium being highly spoken of for design and equipment. Hospital isolation is becoming more and more popular, and of 265 admissions during 1886, 251 were from scarlatina; that is to say, from a disease mainly affecting young children, as to whose removal from their homes difficulties are so frequently alleged by those authorities who have made no proper provision for their reception. The report in question contains a large number of valuable tables and diagrams, and it explains in detail the general measures of sanitation which have, with success, been carried out during the year.

Winchester Urban District.—Mr. Langdon gives a graphic account of the danger from small-pox which communities incur through the unvaccinated state of gipsies. Small-pox encampments were last year established near the city, and the announcements made by the sanitary authorities as to the existence of small-pox amongst the gipsies practically broke up the Lent Fair, which would otherwise have been the cause of much danger. But it is stated that, owing to an announcement in a local paper, some 400 people from Winchester visited the small-pox camp, and Mr. Langdon points out that the well-vaccinated state of the community alone protected them from infection. As regards the gipsies themselves, their failure to procure vaccination has been solely a matter of carelessness, and they gladly availed themselves of the offer of protection. At the gipsy camp no unvaccinated person escaped infection, and none who had recently been successfully vaccinated took the disease. The death-rate in the whole district from all causes was 18·0 per 1000 during 1886; the zymotic rate was 2·8.

Barnstaple Urban District.—Dr. Mark Jackson reports a birth-rate of 29·7 and a death-rate of 17·7 per 1000 for 1886. Neither small-pox, measles, nor scarlet fever caused a single death, the largest item amongst the so-called zymotic diseases being eight deaths from diarrhœa. In relation to five deaths from diphtheria, Dr. Jackson speaks of a prevalence of throat affections generally, the milder disease probably rendering the individual more liable than he otherwise would be to an attack of true diphtheria. The general record of sanitary work in progress is satisfactory; but there is no infectious hospital. Such a building should be provided, and the caution not to let the matter stand over until an emergency arises should be borne in mind. A disinfecting apparatus is in contemplation. Properly speaking, it should stand on the future hospital site, where it would be available for town and hospital purposes.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5605 births and 4128 deaths were registered during the week ending August 20th. The annual rate of mortality in these towns, which had been 22·9 and 23·7 per 1000 in the preceding two weeks, declined last week to 23·3. During the first seven weeks of the current quarter the death-rate in these towns averaged 22·2 per 1000, and was 1·0 above the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 15·0 in Derby, 16·9 in Norwich, 17·1 in Halifax, and 18·2 in Leicester. The rates in the other towns ranged upwards to 29·9 in Birkenhead, 30·1 in Preston, 30·8 in Blackburn, and 33·5 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined from 1301 to 1252 in the preceding three weeks, further fell last week to 1195; they included 878 from diarrhœa, 100 from whooping-cough, 87 from measles, 61 from scarlet fever, 35 from "fever" (principally enteric), 30 from diphtheria, and 4 from small-pox. These zymotic diseases caused the lowest death-rates in Halifax and Norwich, and the highest in Hull, Brighton, and Portsmouth. Diarrhœa caused the greatest mortality in Salford, Brighton, Hull, Birmingham, and Portsmouth; measles in Manchester, Bradford, and Oldham; scarlet fever in Bristol and Blackburn; whooping-cough in Cardiff, Sunderland, and Blackburn; and "fever" in Cardiff and Huddersfield. Of the 30 deaths from diphtheria in the twenty-eight towns, 22 occurred in London and 2 in Liverpool. Small-pox caused 4 deaths in Sheffield, but not one in London or in any of the twenty-six other large provincial towns. Only 3 cases of small-pox were under treatment on Saturday last in the Metropolitan Asylum Board's hospitals receiving cases of this disease, of which one was admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 158 and 175 in the preceding two weeks, further rose last week to 178, but were 3 below the corrected average. The causes of 79, or 1·9 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Norwich, Leicester, Salford, Sunderland, and in five other smaller towns. The largest proportions of uncertified deaths were recorded in Newcastle-upon-Tyne, Sheffield, Oldham, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·1 and 19·3 per 1000 in the preceding two weeks, delined again to 18·6 in the week ending August 20th; this rate was 4·7 per 1000 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 13·3 and 15·1 in Aberdeen and Greenock, to 21·1 and 34·2 in Perth and Paisley. The 464 deaths in the eight towns last week showed a decline of 18 from the number in the preceding week, and included 44 which were referred to diarrhœa, 24 to whooping-cough, 12 to scarlet fever, 6 to "fever," 1 to diphtheria, and not one to small-pox; in all, 87 deaths resulted from these principal zymotic diseases, against 73 and 81 in the preceding two weeks. These 87 deaths were equal to an annual rate of 3·5 per 1000, which was 3·2 below the mean rate from the same diseases last week in the twenty-eight English towns. The fatal cases of diarrhœa, which had been 28 and 37 the preceding two weeks, further rose last week to 44, of which 11 occurred in Glasgow, 10 in Paisley, 9 in Edinburgh, and 6 in Dundee. The 24 deaths referred to whooping-cough showed a decline of 4 from the number in the previous week, and included 6 in Glasgow, 5 in Edinburgh, 4 in Dundee, and 4 in Greenock. The 12 fatal cases of scarlet fever showed a further increase upon recent weekly numbers, and included 6 in Glasgow and 5 in Dundee. The

Digitized by Google

deaths referred to "fever," which had been 9 and 1 in the preceding two weeks, rose again to 6 last week, of which 4 occurred in Glasgow. The fatal case of diphtheria was recorded in Dundee. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 67 and 71 in the previous two weeks, were 69 last week, and exceeded by 7 the number returned in the same week of last year. The causes of 53, or more than 11 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 29·6 and 31·5 per 1000 in the preceding two weeks, further rose to 35·5 in the week ending August 20th. During the first seven weeks of the current quarter the death-rate in the city averaged 30·3 per 1000, the mean rate during the same period being but 22·5 in London and 18·8 in Edinburgh. The 240 deaths in Dublin last week showed an increase of 27 upon the number returned in the preceding week; they included 39 which were referred to diarrhœa, 27 to measles, 5 to whooping-cough, 4 to "fever" (typhus, enteric, or simple), 3 to scarlet fever, and not one either to small-pox or diphtheria. Thus the deaths resulting from these principal zymotic diseases, which had steadily risen in the preceding five weeks from 45 to 58, further rose last week to 78; they were equal to an annual rate of 11·5 per 1000, the rate from the same diseases being 5·7 in London and 3·2 in Edinburgh. The fatal cases of diarrhœa, which had been 29 and 23 in the previous two weeks, rose again to 39 last week. The deaths referred to measles, which had been 16 and 27 in the preceding two weeks, were again 27 last week. The 5 fatal cases of whooping-cough were within one of the number in the previous week, and the 4 deaths referred to "fever" exceeded those recorded in any recent week. The deaths of infants showed a marked excess, while those of elderly persons declined. Eight inquest cases and 8 deaths from violence were registered; and 51, or nearly one-fourth, of the deaths occurred in public institutions. The causes of 49, or more than 20 per cent., of the deaths registered during the week were uncertified.

THE SERVICES.

WE learn from the Indian papers that Surgeon J. C. Addison, of the Army Medical Staff, has, with the sanction of the military authorities, established an Ambulance Association at Quetta, and has been delivering a course of lectures on "First Aid to the Wounded." His class consisted of twenty-four ladies and a large number of the officers at the station.

WAR OFFICE.—Army Medical Staff: Brigade Surgeon Albert Stanley Knight Prescott has been granted retired pay, with the honorary rank of Deputy Surgeon-General (dated July 26th, 1887); Surgeon-Major Samuel Flood is granted retired pay, with the honorary rank of Brigade Surgeon (dated Aug. 24th, 1887).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon John Shields has this day (16th inst.) been placed on the retired list, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets. Fleet-Surgeon Fleetwood Buckle, M.D., has been placed on the retired list of his rank (dated Aug. 12th, 1887).

The following appointments have been made:—Fleet Surgeon H. S. Lander, to Devonport Dockyard; Fleet Surgeon S. H. Stewart, to the *Impregnable;* Fleet Surgeon J. B. Courtenay, to the *Clyde;* Staff Surgeon E. R. H. Pollard, to the *Ganges;* Staff Surgeon S. F. Hamilton, to the *Devastation;* Staff Surgeon C. Hicks, to the *Neptune;* Surgeons G. B. Townsend and H. J. Hadden, to the *Nelson*, additional; Surgeon P. J. Barcroft, to the *Revenge;* Surgeon F. R. Jeans, to the *Monarch;* Surgeon R. W. Rickards, to the *Hotspur;* Surgeons G. H. Milnes and C. H. Upham, to the *Alexandra*, additional; Staff Surgeon J. C. B. Maclean, to the *Agincourt;* Staff Surgeon D. D. Birkey, to the *Espiegle;* Staff Surgeon E. H. Saunders, to the *Garnet;* Staff Surgeon William R. White, to the *President*, additional, for temporary service; and Mr. R. A. Nesbitt to be Surgeon and Agent at Donaghadee, Orlick Hill, Millisle, and Ballywater.

RIFLE VOLUNTEERS.—4th Volunteer Battalion, the Gordon Highlanders: James William Mackenzie Gunn, M.A., M.B., to be Acting Surgeon (dated August 20th, 1887).—2nd Volunteer Battalion (the Prince of Wales's), North Staffordshire Regiment: Surgeon H. M. Morgan, M.D., is granted the honorary rank of Surgeon-Major (dated August 20th, 1887).

Correspondence.

"Audi alteram partem."

"USEFUL EMPLOYMENT IN THE TREATMENT OF THE INSANE."

To the Editors of THE LANCET.

SIRS,—Writing under the above heading in your issue of August 20th, Dr. Bower is good enough to refer in complimentary terms to the management of this hospital. His letter, however, contains at least one, doubtless inadvertent, inaccuracy, which, I feel sure, he will be pleased to see corrected. He conveys the impression that the system of employment of patients is here of quite recent development, and adduces want of premises as an explanation of our apparent tardiness and want of energy. In both these particulars he is entirely in error. This institution has for many years had immediately attached to it an estate of nearly seventy acres (ornamental grounds, flower and kitchen gardens, &c.), and been equipped with the usual complement of workshops and the like. It is obvious, therefore, that it has not lacked the necessary resources. As to the utilisation of this material, it is certain that, during the tenure of office of the present medical superintendent (a period of over twenty years), employment of patients, particularly in out-door work, has been regarded as a remedial agent of the most radical importance, and been carried out to the fullest possible extent. The case-books and other hospital records at any time during the past ten years indicate a proportion of working patients nearly, if not quite, as high as at present. It is true that the purchase, seven years ago, of an annexe, with a farm of 500 acres, has in a measure favoured the development of the employment system, but in no sense originated it. It has rendered practicable the devising of greater variety in occupation, but has not materially increased the number of the workers.

In a paragraph of their Forty-first Annual Report, the Commissioners in Lunacy note with approval the fact that one-third of our male patients were employed in out-door work in April, 1886. This estimate is, of course, perfectly correct so far as it goes, but it does not entirely cover the ground. In illustration of my meaning, I beg leave to append statistics, as to occupation, of a day taken at random in the past week:—

Total number of male patients	164
Employed on farm, grounds, and gardens ...	60
" in in-door work (carpentry, printing, tailoring, &c.)	19
Cricket, tennis, bowls, driving, fishing, &c. ...	15

The addition of the inside workers to those employed out of doors raises the number of those usefully occupied to 79, or nearly 50 per cent. In-door work, though for obvious reasons less beneficial than labour in the open air, is nevertheless resorted to in a small minority of instances—patients who are either strongly averse to, or physically unfit for, out-door employment.

Considering next the 15 who are entered as devoting their time to various forms of recreation, I may remark that the majority, if not all, of these individuals are both mentally and physically capable of engaging in manual labour, if it were insisted on. Their preference, however, for healthy amusement in place of actual work cannot under the circumstances be reasonably interfered with. In a pauper asylum, however, where such counter-attractions are practically non-existent, this class of patients would undoubtedly go to swell the ranks of the usefully employed.

When to the numbers already quoted, I make two further additions—to include, first, those who are incapacitated by bodily illness or physical infirmity, and, secondly, those who, without pretending to any regular employment, yet occupy themselves in a rational manner in the wards (reading,

Digitized by Google

writing, drawing, music, &c.),—I find, out of a total of 164 male patients, a residuum of not more than 20 who can be truthfully denominated as hopelessly idle. These are either incurably indolent, or else so demented or intractable as to baffle all efforts to improve them.

Taking into account the comparatively large number of patients, the classes of society from which they are drawn, the various difficulties in the way of enforcing such a plan of treatment, amongst which the ill-advised opposition of relatives and friends is one of the most practical and embarrassing, the result which I have endeavoured to indicate above is not, I venture to think, wholly unsatisfactory.

I am, Sirs, faithfully yours,

LLOYD FRANCIS, M.A., M.D. Oxon.,
Senior Assistant Medical Officer.

St. Andrew's Hospital, Northampton, Aug. 23rd, 1887.

"DIPHTHERIA IN MAN AND THE LOWER ANIMALS."

To the Editors of THE LANCET.

SIRS,—In a leading article on the above subject in your issue of the 13th inst., you draw attention to a report lately issued by Dr. Turner, in which he deals with the relationship that, according to him, exists between diphtheria of man, the horse, the cow, the pig, and poultry, I have not at present seen Dr. Turner's report, but I am, nevertheless, bound to accept the statement in your article as in some sense reflecting the general conclusions with which it deals.

Dr. Turner seems to have arrived at the conclusion that the disease so well known to veterinary surgeons as affecting poultry, and in which a false membrane is formed in the mouth, throat, nostrils, and conjunctivæ, is identical with diphtheria, and he speaks of the membranous product as being *found in the trachea*. At first sight does this statement bear out the relationship? I have always understood that diphtheria is, in the human subject, mainly localised in the pharynx and fauces, and if I am wrong in this ingrained supposition, I may still fall back upon my experience, and say that I have never yet seen anything approaching a diphtheritic product in the trachea of any feathered creature; but I will not beg the question thus, as I am perfectly well aware that circumstances alter cases, and that slight histological differences exercise a material influence in the characters of pathological or, more strictly speaking, histological processes. I cannot at the moment remember the name of the pathologist who some time ago stated that the difference between catarrhal, croupous, and diphtheritic products was merely histological, and was dependent upon the difference in the arrangement of the epithelium in the mucous membrane of the pharanx, larynx, and trachea respectively, and that the same disturbing influence (only in a different degree) that would produce catarrh or croup in one would produce diphtheria in another; and until this statement was published I was at a loss somewhat to account to my pupils for a fact which I had on more than one occasion observed—viz., the occurrence of true diphtheritic products in the larynx and trachea of the cow. Diphtheria I have only seen once in the horse; it is more common in the pig; and a few years ago cases occurred in swine and cattle in the practice of Mr. Campbell, F.R.C.V.S., Kirkcudbright, on farms where diphtheria *had prior existence* in the attendants. Such statements as that made by Dr. Turner to the effect that "strangles in the horse appears to have some real kinship with human diphtheria" are gratuitous assumptions, and not borne out by the experience of every-day practice. That strangles in some seasons takes on protean characters is a fact well known to all observant veterinary practitioners; that it bears in its essential characters any resemblance to, or has any clinical kinship with, diphtheria are, again, gratuitous assumptions, and all the more so seeing that Dr. Turner attempted to impart to them an air of plausibility by the following statement that "a large proportion of fatal attacks of diphtheria has also been observed to occur in other families of persons—such as shepherds [this ringing the innocent sheep], grooms, and blacksmiths—who have to do with the lower animals." Really this is drawing conclusions (if I may be permitted to say so) from false data with a vengeance. Why does he not put dairymaids and swineherds in the list? Dr. Turner, it seems to me, has lost sight of a well-known law bearing upon diseases and endemics and epizootics and epidemics, to the effect that in certain seasons this class of affections rage simultaneously, and that the same forces which favour the production or prevalence of epidemics and endemics are equally operative in the propagation and spread of epizootic and enzootic diseases. Returning to Dr. Turner's primary argument as to the prevalence of diphtheria in poultry and pigeons, I may be forgiven when I express the doubt that he has not made himself acquainted with the current medical and veterinary literature on the subject during the past few years, both in this country and on the Continent.

About the year 1865, I saw, in the neighbourhood of Liverpool, cases in poultry which I looked upon as of the nature of *diphtheritic aphtha*. On my removal to Edinburgh (in the years 1871-2), I came across similar cases in pigeons, poultry, and canaries, and in the first lectures it was my privilege to give in the Royal Veterinary College on the subject of infectious and contagious diseases I described an affection that I considered partook partly of the nature of aphtha and partly of that of diphtheria by the dual term *diphtheritic aphtha*, and which was most certainly contagious and infectious between poultry and pigeons. I further attributed it to the action of a fungus (a leptothrix), and thought that its production was favoured by insanitary conditions and all influences that tended to lower the vital forces, such as damp, cold, and in-breeding. Some time after this a disease was described by Dr. Fleming, in his "Sanitary Science and Police," under the head of "Gregarinosis" or "Psorospermiosis," the clinical characters of which resembled those of diphtheritic aphtha. The terms mentioned were, if I mistake not, of continental origin, and were applied to the disease because it was believed to be due to a form of psorosperm or gregarina.

In 1879 M. Megnin described diphtheria of poultry, and distinguished two forms — (1) a false membranous form, and (2) a tuberculous form, the former being localised in the pharynx, nose, &c., the latter in the internal organs and muscles; and Megnin identified the disease (histologically) with the hepatic tuberculosis of rabbits. Megnin also asserted that M. Nicati sought to identify the affection with the diphtheria of man; but he himself combated Nicati's identification by drawing attention to the fact that he had frequently seen women and children eat infected poultry with impunity, and by the experiments of Trasbot of Alfort, who inoculated pigs and dogs ineffectually, fowls successfully, and who stated that a pupil of his—M. Faiés—placed diphtheritic membrane (from fowls) in his own throat with impunity.

In May, 1882, I read a paper on "Specificity in Disease" at a meeting of the North of England V. M. Association held at Newcastle, and amongst other subjects touched upon the disease designated "gregarinosis." For some time I had had doubts as to the nature of the disease, and strongly suspected that causally—as most certainly pathologically—it was intimately related to tuberculosis; but there were certain differences in the characters of its local manifestation which I could not reconcile with those of the last-mentioned disease. These were principally the presence of flattened yellow bodies in the intermuscular connective tissue, the peculiar croupous transformations so frequently seen in the lungs, and the cylindrical croupous and hæmorrhagic masses sometimes forming in and occluding the intestines, with the absence of that marked tendency to calcification so characteristic of tubercular granulomata. In the paper alluded to I concluded my remarks as follows:—"The dissemination of the nodules internally is certainly similar to that of ordinary tubercle, and, as in that disease, death is largely produced by anæmia and exhaustion. But, in other respects, the two diseases differ widely, though one is undoubtedly quite as specific in its nature as the other."

Since the above-mentioned date I have arrived at the conclusion that the disease might be due to a cladothrix form of fungus, the visible products of whose action were, as in the case of actinomycosis, granulomata. In August, 1883, attention was directed to the subject of Tuberculosis in Fowls, in a leading article in THE LANCET. And again in October, 1884, the statement of Emmerich to the effect that he had discovered a bacterium in the false diphtheritic membrane from pigeons is noticed in THE LANCET. The spread of disease amongst domestic poultry has been going rapidly on for some years, and in several—in fact, I may say in all—specimens examined by the newer methods of staining, my colleague, Professor McFadyean, has succeeded in detecting bacilli identical with those of tubercle. Whether, however, there are two distinct forms of disease in poultry,

Digitized by Google

a diphtheritic and a tuberculous, or one disease manifested in different ways clinically, must be left an open question; but of the widespread prevalence of tuberculosis in the feathered tribe there can be now little doubt. An admirable article on this subject appeared in the *American Journal of Comparative Medicine and Surgery* for October, 1886, by Dr. Bland Sutton; it was entitled "Avian Tuberculosis."

I am, Sirs, your obedient servant,

Edinburgh, August, 1887. THOMAS WALLEY.

THE ALLEGED CASE OF ASIATIC CHOLERA AT NEWTON-POPPLEFORD.

To the Editors of THE LANCET.

SIRS,—You will probably think the following case of sufficient importance for insertion in an early issue of your valuable journal.

At 7 A.M. on Saturday the 23rd ult., I was called on to visit John F——, aged sixty-seven, a small farmer residing at Newton-Poppleford in the parish of Aylesbeare, distant about nine miles from Exeter. I was well acquainted with the man, who was strong, and enjoyed uninterrupted good health. Formerly he had been rather intemperate, but of late years had been what would be called a "moderate drinker." On my arrival at 9.30 A.M., I was informed that, after a light supper of bread and cheese and a single glass of ale, he retired to rest at 9.30 (his usual hour) on the previous evening, apparently perfectly well. At 1.30 A.M. on Sunday (eight hours before my arrival) he was seized with sickness, which was speedily followed by copious relaxation of the bowels, and in about an hour cramp in the upper and lower extremities set in, and increased with the purging and vomiting until my arrival. No stools or vomicæ had been preserved. The former were described as "at first like dirty water and then light yellow," and the vomited matter as "thick and brown," except when he took tea or milk, which was ejected as soon as swallowed. I found him prostrate and restless; features pinched; eyes sunk; the whole surface of his body bore a marked leaden hue, covered with a cold, clammy sweat. His voice (which I heard, and which forcibly struck me as I ascended the stairs to his room) was completely changed into a whine or loud whisper. His respiration was difficult, and the breath and tongue quite cold. The toes and fingers—the skin of which was much pinched—were severely contracted during the cramps, and the muscles of the calf "quivered" during the absence of cramp. He complained of no griping in the bowels, but of great uneasiness at the epigastrium, severe thirst, and craving for cold water, which was allowed *ad libitum*, but instantly thrown up. Pulse small, thready, and rapid. Temperature in the mouth (taken with great difficulty, and not to be relied on) 98°. At 10.30 P.M. I again visited him, in company with my son (Mr. Bingley G. Pullin). The colour of the body was very livid, the eyes more sunk, the face more pinched, and the hands sodden, as if long immersed in water. Pulse not perceptible. Body covered with sweat of icy coldness. There was at this time a slight return of heat in the breath and tongue, and the purging and sickness had been less severe with the medicine, and he had dozed for a few minutes at a time, but he was now very prostrate and restless, rolling from side to side with severe cramps. Three stools had been reserved, which closely resembled thin gruel or rice-water. The patient stated that no urine had passed during the attack, but about one ounce was taken, which in his struggles was spilt and the opportunity to analyse lost. My son remained to ensure the necessary remedies being carried out. All, however, was of no use, and the patient succumbed at 2.30 A.M. on Sunday (twenty-five hours from commencement of attack). It was not until an hour before he died that stupor set in and his mind gave way. The contraction of the muscles of the calf continued for two hours after death, and during this period the temperature of the body had risen, but in three hours rigor mortis had powerfully set in. The treatment consisted in the first instance of three grains of calomel placed on the tongue, with ten minims of dilute sulphuric acid and ten minims of tincture of opium, every hour, and subsequently diffusible stimulants of ammonia and ether, with friction and chloroform liniment.

The dwelling was isolated and elevated, and both it and its surroundings were sanitarily satisfactory and the water pure. No diarrhœa prevailed in the family or village, and none has appeared since. It will be asked, What was the cause of the attack? Was it the result of a "specific poison"? I leave wiser heads to determine this point. There was no premonitory stage. It manifested itself suddenly in a most virulent manner, and, as is usual, as far as my experience goes, such cases invariably prove fatal. That the intensity of the attack was determined by the heat of the day, I feel no doubt. During his work on the previous day he came into his house three times to shelter himself from the effects of the sun—quite an exceptional circumstance; and the temperature taken in the neighbourhood that day by one of the most reliable meteorologists (Dr. Radford) was 139° in the sun—a heat never registered higher in the neighbourhood before, and only once so high. I consider it to have been a case of Asiatic or malignant cholera, and to guide me in this opinion I have the advantage of the experience of the severe cholera epidemic of 1849, when I acted professionally under the then Government General Board of Health at Portsmouth, Plymouth, and Cornwall. No symptom that I witnessed during that epidemic was wanting in this case. A post-mortem examination was refused. I may mention that the coffin was saturated with Burnett's fluid, and the corpse wrapped in cloths saturated with Calvert's strong carbolic acid, and interred in forty-eight hours. The bed, bedding, and everything used during the illness I insisted on being burnt at once, the house powerfully fumigated, and the entire premises thoroughly cleansed.

I am, Sirs, yours faithfully,

THOS. H. S. PULLIN, M.D.,

Sidmouth, Aug. 23rd, 1887. Medical Officer of Health for Sidmouth.

"PAIN AND ITS INTERPRETATION."

To the Editors of THE LANCET.

SIRS,—With your indulgence I would offer a few words in reply to Dr. Collins' letter in your last issue. I am not quite sure how that letter should best be answered, but certainly the worst way would be to imitate its method. No good purpose can be promoted in that way. The burden of this letter is in two remarks. The first is that my statements concerning pain "are so strangely at variance with universal experience and common sense that it is incumbent upon anyone who has read them to controvert them." Now, my answer is that I have the best proof possible that Dr. Collins' knowledge is at fault concerning universal experience, and I fear uncharitable as regards common sense; for I have from utter strangers and from all parts of the country the most unqualifying encouragement to continue my papers on the Interpretation of Disease, and this last paper on Pain has been received most favourably. I have had many private letters concerning it; it has been quoted *verbatim* by several provincial papers, with very pertinent and encouraging comments; and what I esteemed perhaps more than all this was your own annotation in the same issue, which very distinctly asserted the beneficence of pain.

I trust Dr. Collins will credit me that I am not anxious to entertain any theory of pain that is wrong or unreasonable, but I must say that there is nothing in his letter to convince me that this beneficent view of pain is wrong. The assumption of universal experience and a private property in common sense is scarcely safe, and any *ipse dixit* based on such disposition is sure to be largely discounted. I must be held excusable, then, if I say I still adhere to every word of my paper. When Dr. Collins charges me with not excepting malignant diseases he does me an injustice. I did make distinct reference to these "apparent exceptions"; no person at all thinking of the matter could escape so doing. But he takes no notice of my attempt to reconcile these with the beneficence of pain. This is unfair and unfortunate; for as long as the philosophy of disease is treated in that manner, so long will our profession remain under an *opprobrium medicinæ* worse even than cancer. I have nothing to do at present with the "wider sense" in which pain may be viewed. I am only concerned with the individual, and I am not afraid that anything determined right for the individual shall be found at variance with the wider signification of pain when that is adequately declared and understood. As to Dr. Collins' own rendering of the matter, which I honestly confess I did not understand,

Digitized by Google

Daily News seems to me to have touched it off quite neatly and gently.

Surely this most important question can be rationally discussed so that some clear understanding may be come to. There are to my own knowledge not a few able men quite clear on the purpose of pain. They may have something to say.

I am, Sirs, your obedient servant,

Brockley, S.E., Aug. 22nd, 1887. H. CAMERON GILLIES.

CASE OF HYSTERICAL SPASM SIMULATING TETANY.

To the Editors of THE LANCET.

SIRS,—In connexion with the above subject, reported by Dr. F. F. Caiger in your issue of Aug. 20th, I think the following will be read with interest by many neurologists.

M. P——, female, aged twelve years, a provisional pauper, came under my notice about the end of last June with symptoms of gastro-intestinal disturbance, produced—as is so commonly the case, especially at this season of the year—by taking food of bad quality and in insufficient quantity. She lives in one of the lowest parts of a provincial town, amidst bad sanitary surroundings. The house she lives in is an ordinary cottage, and, besides the family, accommodates one or more Irish lodgers, and is in a very dirty state. My patient is a bright, intelligent little girl, with fair hair and blue eyes, small and slightly made, and with a pinched face and subdued manner. There is no evidence of syphilis or worms, nor has she ever had any catamenial discharge. During the winter months she nursed a younger brother through an attack of scarlatina, and when in her usual health she does most of the housework. She attended the surgery from time to time, complaining of occasional vomiting, pain behind the sternum and in the abdomen, and constipation, and was treated with a mild saline purgative and a few drops of opium. She came to the surgery for the last time on August 8th, and on the 9th, about 7 P.M., I received a message to go at once, as she was "in fits." I attended almost immediately, and when I opened the door the following scene met my gaze. On a bed under the window of the living room into which I entered, and close to a great fire where culinary operations were going on, lay my patient, surrounded by six or seven dirty women and two or three dirty men, each of whom was holding some different part of her body. She was quite still when I entered, and watched me approach her; but as soon as I touched her the following convulsion occurred. The depressors of the lower jaw contracted, opening the mouth to its fullest extent, the facial muscles attached round the mouth contracted, fully exposing the teeth in both jaws. As soon as this action was completed the post-cervical muscles commenced to contract, and drew back the head until the tip of the nose rested on the pillow. The wave of contraction then passed slowly down the spinal muscles; the thorax bulged forward, then the abdomen, and then the legs became rigid. Although the child is not more than four feet six inches in height, I think I shall be well within the mark in saying that the lumbar region rose twelve inches from the bed, and she rested solely on her forehead and heels. The legs were now drawn up, and then violently extended. This had the effect of forcing the face upwards against the iron bed-head, and had not her shoulders been raised into a semi-erect position, the face would have been seriously injured against the iron rail (as happened once or twice to a slight extent). The spasm seemed now to attack the remaining muscles, and the consequence was that the whole body became rigid and straightened out, with the head thrown back. The spasm began now to pass off, leaving one side sooner than the other, thus producing pleurothotonos, with the concavity towards the left. The whole attack lasted two or three minutes, and was repeated several times during the night, all being very much alike by varying in slight details. It was impossible to take the temperature. I came to the conclusion that the case was hysterical, and—my suggestion that the case would be better treated in the workhouse hospital not meeting with any opposition—I enjoined strict quiet in a cool room, from which all visitors were to be rigorously excluded, and left without ordering any other treatment. The next day, Wednesday, I found that the convulsions had continued through the night, and were, if anything, more severe than when I last saw her. I injected a quarter of a grain of morphia hypodermically, but found later in the day that it had had no effect in checking the convulsions. On Thursday, the 11th, I found her still in convulsions, and much exhausted; the convulsions, I was informed, had continued at intervals since my last visit. I ordered her a mixture containing five minims of tincture of Calabar bean and ten grains of bromide of potassium every two hours. On the 12th I was told that my patient took the mixture with great difficulty, and complained of its being very salt. From her general expression and semi-somnolent manner, I began to fear that, after, all I had to do with commencing meningitis, and, there being some constipation, I gave her two powders at intervals of three hours, each containing a little calomel and half a minim of croton oil, which operated promptly and without causing any disturbance. When I saw her in the evening, she was not convulsed, but pressure on the ovarian region induced a pretty severe convulsion. On Saturday, the 13th, I heard her screaming as I came up the street—"Oh, mother! Cut my legs off. Oh, my legs and my back! Mother, be quick!" As soon as she ceased to cry out she went into a convulsion similar to the one I have described. She appeared quite unconscious of what went on around her, and after giving orders for the mixture to be pushed I left. On Sunday, the 14th, I found her singing, shouting, and beating time with her arms and legs, heedless of all that went on around. I was told that she had slept well during the night, and awakened seemingly all right, but that on an attempt being made to give her the mixture the present state of things commenced. The attack passed off during my visit, giving me an opportunity for the first time of taking her pulse (80) and temperature (98·8°). I now became satisfied that I had to do with hysteria, and thereon determined to stop the mixture and watch the progress of the case. Later on in the day, at the urgent request of her friends that I should give her something, I sent a mixture of burnt sugar and water, and was informed on my next visit, when I found her perfectly quiet and sensible, that it had done her a deal of good, and that she had not had a single attack since taking the first dose. I took this opportunity of informing her friends in her hearing that I declined having anything more to do with the case, and that if she had any more convulsions I should insist on her going to the workhouse. Since that time I have heard nothing of her.

I am, Sirs, yours faithfully,

Barnsley, Aug. 24th, 1887. EDWARD KERSHAW.

EIGHTEEN MONTHS' TRIAL OF CANTANI'S TREATMENT OF CONSUMPTION.

To the Editors of THE LANCET.

SIRS,—Your admirable leader on Bacterio-therapy in your number for July 23rd last deserves not only the attention but the careful study of medical men. It is a garden of valuable suggestion, and contains the rich fruits of extended experience.

When discussing the erysipelas streptococcus injections of Fehleisen and the bacterium termo inhalations of Cantani, you write "Cantani's method has proved a failure," and then you give Dr. Pawlowsky's explanation of the cause of that failure—viz., "the confusion of many species of bacteria under the head of bacterium termo," and you add, "also the reliance solely upon the antagonism of these two organisms, the bacterium termo and the tubercular bacillus, as sufficient to cause the destruction of the latter." Pawlowsky's explanation and your additions are instructive and reasonable, but, these exceptions being removed, experience leads me to disagree with the conclusion that "Cantani's method has proved a failure." In the previous part of your article I read: "On all sides we hear of bacillicidal methods, but the results are not commensurate with the faith that inspires them or the plausibility of the grounds on which their employment is based.... and yet we by no means despair of a way being found out of the morass." And you continue: "That way lies, we think, in affording to the organism support sufficient to cope with the bacterial hordes—in other words, to strengthen the powers of vital resistance." Did I try to describe to you the system which I have pursued in the treatment of consumption for the last eighteen months, I could not adopt more suitable language

Digitized by Google

than that which your suggestion employs. I have made Cantani's bacterium termo the basis. In a letter which I received from him occur these words: "Le B. termo, qui m'a servi si bien contre la phthisie, est une espèce particulière du genus Termo, qui végéte bien à 39-40 C°. On doit si le procurer dans un laboratoire bactériologique et le cultiver toujours pur." Here are four particulars: (1) a particular species; (2) a particular laboratory; (3) a particular temperature; (4) a particular cultivation. To avoid the confusion of species which Pawlowsky condemns, minute attention to these particulars is requisite; and no one who has not diligently tried can estimate the trouble of sterilising the suitable fluid and thus sowing that bacterium, and the number of times it is necessary after every precaution to go over and over the same ground to secure the culture of one species, and one species alone; and yet this point secured is only the beginning. To find the way out of the morass, too much attention cannot be paid to your direction—viz., "to afford to the organism support sufficient to cope with the bacterial hordes—to strengthen the powers of vital resistance." To secure this end, every means within my reach has been resorted to—nutritious food, tonic and strengthening medicines, daily inunctions of cod-liver oil, thorough ventilation of apartments, disinfectants, change of air, long continuance in the open air, and, latterly, the addition of the sulphuretted hydrogen rectal injections of Bergeon.

Now for results. Were I to send you a table or chart describing cases from the commencement to the conclusion, it would claim too much of your space. Suffice it to say, I can point to patients, not only in Liverpool, but in London and various other places—patients, the first account of whose symptoms would have left no ray of hope under the old methods of treatment; patients, now convalescent, who were pronounced to be in advanced phthisis by other physicians before bacterium termo and vital restoratives combined yielded the wished-for consummation. The desire that similar success may attend the efforts of others induces me to write thus. Truly the morass is a deep one. It is daily engulphing victims; but there is a way out, and some have securely walked it. To induce others to try the path you advocate is my apology for thus intruding on your valuable space. I am, Sirs, yours faithfully,

Liverpool, Aug. 23rd, 1887. W. H. LAMBART, M.D., F.R.C.S.

P.S.—It will give me pleasure to supply, free of charge, a pure cultivation to any medical brother who is anxious to give this treatment a fair trial.

THE PASTEUR COMMITTEE.

To the Editors of THE LANCET.

SIRS,—It may appear to be presumptuous on the part of so humble a member of the profession as I am to record my objection to the report of the committee appointed to inquire into the value of Pasteur's method. Nevertheless, I feel sure many will agree with me that the report is not satisfactory so far as the main question at issue is concerned. The committee appear to have experienced no difficulty in obtaining facilities for experimentally testing the *prophylactic value* of Pasteur's method, but what I think required to be shown in the same manner was whether it possessed *antidotal powers*. No attempt whatever seems to have been made to submit this matter to experimental test. It is true that the committee offer an opinion, but it is founded upon a critical analysis of Pasteur's cases. Even supposing the committee had met most of the principal objections to these cases, which, with all due deference to those eminent gentlemen, I may venture to say appears not to have been the case, their decision, however much entitled to respect, would, after all, only be a matter of opinion. I humbly submit that what is required to be tested by *experiment* is this: (*a*) Does inoculation with Pasteur's material prevent the occurrence of rabies after infection has taken place? (*b*) If so, what is the shortest period after infection that it does so?

Surely, in the absence of any experimental researches, the success of the method as a *remedial measure* is as far from *demonstration* as ever. I am, of course, assuming that the abstract contained in your issue of July 2nd, 1887, from which my information is obtained, accurately describes the report of the committee. More than twenty years' practical experience in investigations of a somewhat similar nature must be my respectful apology for this communication.

I am, Sirs, yours truly,

July 24th, 1887. VINCENT RICHARDS.

THE ORGANISMS OF MALARIA IN THE EAST.

To the Editors of THE LANCET.

SIRS,—It may interest some of your readers to hear that the micro-organisms of the blood supposed to be characteristic of the malarial infection have been found almost daily, for some time past, in two patients at present lodged in the clinical medical wards at the Jamsetjee Jejeebhoy Hospital, Bombay. They have been seen not only by myself in charge, but also by Professors Manser, Macdonald, and Burke. Stained preparations are preserved, and on careful comparison with the original descriptions of Professors Laveran, now of Paris, and Osler of Philadelphia, there seems to be no doubt of the identity of the "hæmatozoa of ague," sometimes at least, found in this part of India, with the organisms now known to prevail in parts of Europe, Africa, and America. Several interesting questions are raised by these recent observations, which can be fully answered only after a prolonged research. Hitherto, after a brief inquiry, it has not appeared to me that the pigmented monads, of either spheroidal or crescentic shape, are usually or distinctly present in the blood of patients affected with the common so-called "malarious remittent" fever of Bombay. Nor have they been detected in four pronounced examples of "malarial cachexia." According to my experience, genuine "ague" here is almost invariably an importation; and as regards the two positive instances above named, it happens that the quotidian and quartan types they represent were acquired outside the limits of the western Presidency. About two years since a fatal case of "pernicious" malarial fever came under my care from the N.W. frontier, and in it the blood was loaded with pigment in a striking degree. (*Vide* Trans. Med. and Phys. Soc., Bombay, No. 8, new series, 1886.)

I am, Sirs, your obedient servant,

Grant Med. Coll., Bombay, July 28th, 1887. H. V. CARTER.

THE STATE OF THE THAMES.

To the Editors of THE LANCET.

SIRS,—Perhaps you may not disdain to receive the congratulations of a simple engineer upon the correct views expressed on several occasions on the above subject by the leading medical journal, and your clear short article in your issue of to-day, the 13th inst., presents a striking contrast to a long and lame apology for chemical failure published by the *Engineer* newspaper on the 5th instant. This paper has devoted many leading articles during the last two years to the advocacy of an ingenious theory set up by Mr. Dibdin, chemist to the Metropolitan Board of Works, and has striven by faint praise of the permanent remedy recommended by Lord Bramwell's Royal Commission to exalt the supposed economy of experimenting with permanganate of soda. These articles contained internal evidence of acquaintance with unreported proceedings of the Board in pursuance of their chemist's advice, which led me to refer to them as "semi-official" in one or two letters published without disclaimer by the *Engineer;* but the article of the 5th inst. has "let the cat out of the bag," and shown that its editor sympathised with the Board so long only as its majority was content to follow the lead of their chemist, and proceeds to taunt the Board with "drifting" towards Canvey Island.

Now, I would ask your readers if it is right that a problem of such public importance as that now before the Metropolitan Board should be treated by anyone in such a spirit as seems to be indicated by the word "drifting," and still more by the following further quotation from the *Engineer* of the 5th inst.:—"Without really intending it, the Board is now playing into the hands of Mr. Bailey-Denton and his colleague."

I am, Sirs, your obedient servant,

ALFRED S. JONES, Assoc. M.Inst. C.E.

Wrexham, Aug. 13th, 1887.

THE UNCONSCIOUSNESS OF LIPSKI.

To the Editors of THE LANCET.

SIRS,—As I gave evidence on the trial that the unconsciousness of Lipski might be caused by mental perturbation, and you have admitted to your columns some very strong remarks thereon, I trust, in fairness to me, you will admit this letter. The positive assertions of your correspondent in your issue of the 20th inst. (page 378) are mistakes, because Lipski in his confession says he *fainted* when he heard the people coming up the stairs. As to the abrasions on the elbows, about which so much has been said, they were caused by the mob seizing him by his bare arms, and trying to drag him from the custody of the two policemen as they were taking him up Batty-street. The abrasions were not there when I found him under the bed. The police just managed to get him as far as my surgery, and took him in for safety. I pointed out to the police the abrasions that the crowd had made. In the interests of persons who, like Simon and Schmuss, in the future may be falsely accused of murder, I hope your correspondent will secure Lipski's case a place "in the records of forensic medicine," so that others may not, like him, seek "in vain for anything that would lend support to such a view" as I took.

Commercial-road, E., Aug. 24th, 1887. J. WILLIAM KAY.

SICILY.

(From our Correspondent.)

THE *Gazzetta Ufficiale* puts it beyond question that in the general stampede from the cholera-stricken communes in this island not only the civil functionaries joined, but also, I regret to say, not a few medical practitioners and pharmacists. These deserters from their posts have each and all been subjected to severe marks of Government displeasure, professors having been deprived of their chairs and divisional surgeons of their appointments. As a foil, however, to this deplorable exhibition of moral cowardice, it is fair to mention that physicians and surgeons from all parts of the island and the peninsula have been besieging the Ministry of the Interior to obtain permission to serve in the cholera-visited localities, the majority of the applicants being young men eager to atone, even by their lives, for the defection of their demoralised brethren. Examples of the stuff of which these medical youths are made might easily be cited, and one of them, whose tragic end absolves me from the duty of withholding his name, I cannot refrain from mentioning. Vincenzo Rapisardo, Sicilian by birth and a medical student of five years' standing, lost no time in enrolling himself among the volunteers in the cholera campaign. Catania was the place to which he was told off, and he worked night and day in relieving patients and in helping forward the sanitary works. Meanwhile the enemy had appeared in force at Paterno, his native village, where his family were still residing. Most of the functionaries of the place, civil as well as medical, had taken flight, when Rapisardo appeared on the scene. He at once took upon himself the work of half-a-dozen hands, visiting the sick, compounding medicines, performing every kind of hygienic duty, and keeping, by constant corrrespondence, the officials at headquarters cognisant of the movements of the disease. Day and night he laboured at his wellnigh solitary task, till he, too, was struck down by the malady, which his strength was too far gone to resist. He died on the 5th inst., and a few days afterwards was followed to the grave by his mother and sister.

An assistant of Professor Bizzozero of Turin is another of these young medical heroes, and him, too, I may mention, as the Government have made public recognition of his work. Dr. Canalis, whose name has before now appeared in your columns in connexion with certain departments of physiological research, received from Signor Crispi, then Minister of the Interior, now Premier of Italy, the mandate to go to Catania directly the cholera had declared itself. To Catania accordingly he went, and in concert with Signor Noghera, official inspector of sanitary works, he organised a thorough system of medical relief and hygienic precautions, exposing himself in a hundred different ways to the malady wherever it was most pronounced, and not leaving the spot until he had made return to it unnecessary. A friend who has lately seen him informs me that what Canalis found more disheartening than the stubbornness of the epidemic was the cowardice of the local authorities and the ignorance of the multitude. He has prepared, and is, I am told, about to publish, an official report of his experiences, and he certainly will not spare those who have failed in their duty, or have been found wanting in common humanity. Moral paralysis is hardly the word for the inaction of the communal functionaries, who, according to Dr. Canalis, allowed from twenty to thirty cases a day to occur almost at their doors, and who were too frightened to inform themselves of the symptoms and to report the same to headquarters. And what is to be done with communes like many of which Dr. Canalis has just had experience?—communes of 20,000 inhabitants, where the pigs patrol the streets and where the population threaten to rise *en masse* and stone the sanitary inspectors who dare to close notoriously infected wells!

Servius, whose commentary on Virgil contains so much information on the life of classical antiquity, tells us that at Massilia (the modern Marseilles), whenever a pestilence appeared, one of the poor offered himself to his fellow-citizens on these conditions; he was to be kept and daintily fed at the public expense for a whole year, and after that he was to be arrayed in verbena and sacrificial vestments and carried through the streets amid the execrations of the people—to make himself, as it were, the embodiment of all the maledictions of the townsfolk—by whom he was finally to be precipitated into the sea. This heathen custom, however, is intelligible and even rational, compared with the madness without method that assails Southern Italy in cholera times. At Risposta, in this island, the other day the countryfolk rose and murdered a man whom they suspected of secretly "propagating the malady." In other Sicilian localities the people openly accuse their priests of distributing "the poison," and post their names as worthy of assassination; and why? Because, amid the general sickness and mortality few or none of these spiritual men have been taken ill or died! On the 14th inst., shortly after midnight, the postal diligence plying between Caltagirone and Valsavoia, had reached a lonely township in the Commune of Granmichele, when it was suddenly stopped by twelve individuals armed with rifles. They presented their firearms at the windows, and commanded the coachman and the guard to deliver the post-bags at once. These they opened, removing the letters and newspapers and certain articles which find hospitality in the post-bags for the use of the military. They touched no other object of value, and even returned the guard his watch, which he had voluntarily given up to them. Mysterious brigands these! But it now appears that they were not gentlemen of the highway at all, but honest countryfolk who thought they were doing a sanitary service by stopping the conveyance of cholera-infected correspondence between their own and the surrounding communes.

Oh for the day when, in the memorable words of Sir James Coxe, the late Scottish Commissioner in Lunacy, every citizen, not in Sicily only, but much nearer home, will be taught at school to be "the intelligent custodian of his own health." Southern Italy has more than her proper share of this educational leeway to make up, but now she is more likely to start fair in that wholesome direction than she has hitherto been—her leading statesman, Signor Crispi, himself the representative in the Italian Chamber of one of the divisions of this city, and now Prime Minister of the kingdom, being an enthusiastic sanitarian, one on whom the mantle of Bertani has worthily fallen, and who will make his term of office memorable by a vigorous carrying into effect of the new "Codice igienico." Under his auspices, reinforced, too, by his reassuring presence, Palermo has suffered but lightly from this return of her old enemy. The municipality, I may add, have shown praiseworthy energy in seconding their distinguished townsman's initiative, and are at this moment organising depôts where good bread and sound meat can be sold to the very poor at prices within the reach of all.

Palermo, Aug. 20th.

AT an inquest recently held at Widnes on the body of a young man who died in consequence of injuries received in a game of football, the jury returned a verdict of accidental death.

MANCHESTER.

(From our own Correspondent.)

VICTORIA UNIVERSITY.

At the late examinations in medicine there were thirty-two successful candidates, twenty-six of whom were students from Owens College, and six from University College, Liverpool. At the Preliminary Scientific five Owens College students and one from University College passed in the first division, and five University and seven Owens men in the second division. At the Intermediate, four Owens men passed in the first division and five in the second. At the Final Examination, Part 1, there were three successful candidates (all Owens College men), and in Part 2 of the Final two from the same College. Arrangements have been made for a continuation of the lectures during the coming winter on the model of the "Cambridge University Extension" lectures. Professor Munro will deliver one course at Withington on the English Constitution, and Professor Boyd Dawkins another on Evolution and Geology.

THE IRWELL AND SEWAGE.

Mr. Walmsley continues to draw attention in the public press by a series of letters to the disgraceful condition of the river Irwell from sewage contamination, urging that all offenders should promptly and thoroughly be brought to book. It is to be feared that one of the greatest sinners is the city of Manchester, and until we get our new sewage scheme in operation little improvement can be looked for. In a letter to-day Mr. Walmsley states that the death-rates of those districts of the borough which abut on the river varies from 25 to upwards of 42 per 1000 per annum, a statement of serious import.

WATER SUPPLY.

Notwithstanding the late acceptable rain, we are still on a limited water supply, and so urgent had the matter become that the corporation were seriously directing their attention to an additional supply from subterranean sources. At some coalpits near Moston, which were flooded a few years ago and rendered unworkable, a quantity of about 4,000,000 gallons is available, and, after examination, has been declared of good quality, though rather hard for manufacturing purposes.

SALFORD FEVER HOSPITAL AND INFECTIOUS DISEASES.

The acquirement of a site for the new Fever Hospital required by the borough of Salford appears to be a matter of some difficulty. The land last proposed to be used for this purpose has now been objected to on account of its proximity to the workhouse hospital, in addition to the objections made by the residents in the neighbourhood of Hope. The epidemic of measles appears now to be subsiding, but scarlet fever still continues very prevalent, notwithstanding the large number of cases sent to hospital, the wards of both fever hospitals being very full of scarlet fever patients. The effect on the death-rate by the large number of fatal cases of measles was apparently very marked last quarter. Manchester occupies the unenviable position of having the highest death-rate in the country for the three months ending July 2nd, being no less than 30 per 1000 per year.

OPEN SPACES.

A wise and philanthropic course has been taken by the dean and canons, who have promised a large piece of land in the populous and increasing district of Newton Heath. The cathedral authorities are possessed of much land in this manufacturing suburb, and while they will be doing a good thing for the dwellers, they will probably lose but little pecuniarily, as it is usually found that the land adjoining parks and open spaces acquires an enhanced value. The Manchester and Salford Sanitary Association have issued their tenth volume of Health Lectures for the People, comprising the last course delivered during the winter 1886-87.

Mr. de Jong, the resident surgeon at the Jubilee Exhibition, has had a considerable number of cases pass through his hands during the past month. On Saturday last a serious case of injury from burns occurred by the careless habit of throwing down lighted matches in the grounds. A lady's dress was thus set on fire, and she was much burnt before the flames were extinguished.

Aug. 23rd.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

SOUTH SHIELDS.

DR. A. CAMPBELL MONRO, medical officer of health for South Shields, has issued his annual report, which is of a satisfactory nature, and shows that during the past year the death-rate was 20·5 per 1000, which is the lowest death-rate in the borough, with two exceptions, since 1872. After pointing out the difficulty of dealing with zymotic cases on account of the small proportion of cases notified to him, Dr. Monro shows that, of 137 persons admitted to the Infectious Hospital, 129 recovered. He points out how the corporation, in converting a large area of waste ground, had made it into a Marine Park second to none in the kingdom. This, with the provision of salt water baths on the most modern principles, had made South Shields proverbially a healthy town and a desirable seaside resort; but he, at the same time, urges on the authorities the view that while the sea side of the town is well provided with breathing and recreation space, the west and crowded end requires their attention before it is built up; for to aged persons and younger children the Marine Park is practically inaccessible. There can be no doubt that "the folk of Shields" possess sufficient public spirit to carry out Dr. Monro's valuable suggestion. At the late annual meeting of the Ingham Infirmary, South Shields, the deepest regret was expressed at the somewhat sudden death of Alderman Williamson, who had laid the foundation stone of the present buildings in May, 1871, and who from that time until his death was president of the hospital, having contributed the munificent sum of over £3000 towards the building, and furnishing funds. It was resolved to call No. 1 ward the John Williamson Ward in future. The Hospital Sunday and Saturday fund showed a small increase over the previous year. It has been decided to erect a monument in South Shields to the lifeboat inventors, Wouldhave and Greathead.

NEWCASTLE-ON-TYNE DISPENSARY.

The vacancy for the honorary physicianship of the Newcastle Dispensary has been filled up, Dr. G. Armstrong Atkinson, after a spirited contest, having been elected. Dr. Atkinson is a brother-in-law of the late Dr. Holland, whose death caused the vacancy. Dr. Atkinson was late assistant to the Professor of Materia Medica and Demonstrator at Edinburgh, and is a distinguished graduate of that University.

A CAUTION.

A successful female swindler has been operating in Newcastle, and the following is her *modus operandi*. Having somehow become aware that a medical man and his family were travelling, she represented to the servant that she was a great friend of her master, and a surgeon's daughter herself; being from her own home in Barnsley, owing to the illness of her mother, she was hastily summoned home, but, being confused and in great anxiety, she had, in changing trains, lost her bag and purse, and was without the means of going home. The servant believed her story, and recommended her to a kind lady patient of her master, who also believed her story, entertained her, and gave her a £5 note and a warm shawl to proceed home. As she will no doubt try to repeat the trick elsewhere, it is as well to say she is about twenty years of age, with good manners and address.

Newcastle-on-Tyne, August 30th.

DUBLIN.

(From our own Correspondent.)

LUNACY IN IRELAND.

FROM the thirty-sixth Annual Report of Lunatic Asylums in Ireland, it appears that insanity throughout Ireland is not only not on the decline, but relatively to a decreasing population quite the reverse, there being a registered excess of 283 at the close of 1886 as compared with the preceding year. With regard to the condition of the 16,077 patients in district asylums on Jan. 1st of the present year, the probably curable, or rather those who admit of hope of

Digitized by Google

recovery, were estimated at 2223, and the incurable at 7779, each class needing an equal professional care and domestic supervision. Owing to a better and more generous treatment of the insane, their longevity is notably increased, so that additional provision has to be made, as shown by the progressive enlargement of public asylums. Twelve years ago the accommodation in them was limited to 7000 beds, which has been increased by over 2600, and even now there is a marked deficiency. During the past year 1831 admissions of patients were effected through magisterial warrants, a method which the inspectors consider as unsatisfactory, and to obviate it they suggest that the Act should be so amended as to impose on the relieving officers in Poor-law divisions an obligation to report on all cases of insanity, so as to have the patients visited professionally and taken charge of in poor-houses until remitted in due form to the asylum of the district. In a total aggregate of 12,618 patients under treatment during the year, 894 deaths took place. The general mortality was owing to pulmonary diseases in nearly a third, or 294 cases; to cerebral affections in 244; debility and old age, 160; diseases of the heart and circulatory system, 37; abdominal derangements, 83; and the remainder to febrile, scrofulous, and cutaneous maladies of no marked description. The cost per head of district asylum patients last year was £20 19*s.* 3*d.*, as contrasted with £21 19*s.* 5*d.* the previous year.

THE PREVALENCE OF OPHTHALMIA IN THE CORK WORKHOUSE.

Dr. O'Farrell, Local Government Board inspector, at a meeting of the Cork guardians last week, reported as to the prevalence of ophthalmia among the workhouse children. He remarks that owing to a great extent to the excellent measures recommended by Dr. Sandford, the outbreak is subsiding; but at no time was the epidemic so severe in its intensity, or in the number of those attacked, as stated in the daily press. He points out that owing to the unhygienic surroundings of the poorer classes, to their overcrowded and smoky cabins, and their impoverished dietary in the past, ophthalmia has at all times been extensively common in this country; and no doubt this tendency to the chronic and milder forms of eye disease has been transmitted from generation to generation. As regards the measures to be adopted to get rid of the present outbreak of ophthalmia, Dr. O'Farrell suggests the appointment of a small committee to consider, in conjuction with the medical officers, how Dr. Sandford's suggestions can be carried into effect, as well as any recommendations which he might make in his report to the Local Government Board. One of the guardians had kindly offered to place a house at Passage West at the disposal of the board for the purposes of isolation, and if the house and situation were suitable, the matter might be referred to the committee for their consideration.

THE DUBLIN HOSPITALS BILL.

It cannot be a matter of regret to all unprejudiced parties to learn that this Bill has been blocked by Mr. Macartney, M.P. The provisions of the proposed Bill, and the constitution of the Board of Management, &c., were so one-sided and unjust, that if carried out, they would have proved so injurious to several well-conducted charitable institutions in this city, that the result above mentioned must be regarded as a subject of congratulation.

Several cases of small-pox have occurred in the town of Drogheda and neighbouring district, and up to the present time one death has taken place.

THE SALE OF DRINK IN FRANCE.—The annual return upon this subject, published in the *Bulletin* of the Ministry of Finance, states that there is a tavern to every 46 inhabitants in the department of the Nord, one to every 55 inhabitants in the Pas de Calais, one to 58 in the Ardennes, one to 60 in the Somme, one to 67 in the Aisne, and one to 75 in the Eure. These are all in the north of France, whereas the five departments in which the taverns and wine-shops are the least numerous, proportionately to the population, are all in the south—viz., the Gers with one in 137, the Vaucluse with one in 159, the Savoie with one in 142, the Hautes-Alpes with one in 143, and the Charente-Inférieure with one in 143. Altogether, there is a tavern to every 95 of the inhabitants throughout France, this representing an increase of more than 11 per cent. within the last six years.

Obituary.

PROFESSOR ADOLF PANSCH.

A DEPLORABLY sudden death by drowning in Kiel Bay on the 14th inst. has deprived German science of one of its ablest representatives. On the morning of that day Dr. Pansch started with his son (a boy of eleven years of age) by steamer to Laboe, to bring back to Keil his sailing boat, with which a few days before he had taken part in the Laboe regatta. Shortly before embarking on the return voyage he complained of feeling unwell, but, nevertheless, set sail with his son about 11.30 A.M. The course of the little craft was sufficiently smooth till between Möltenort and Heikendorf she was struck by a heavy squall and capsized. Dr. Pansch had time to fling the rudder to his son and utter the words "*Rette dich!*" ("Save yourself!") and then sank. Known to be an expert swimmer, and quite equal to finding his way to the shore, he is thought to have died at once from the shock, having for years been a sufferer from organic lesion of the heart. His body was afterwards recovered by one of the eight boats that set out in quest of him. His son had shortly before been saved, though in an extremely exhausted state, by a passing steamer.

Adolf Pansch was born on March 2nd, 1841. From 1860 to 1864 he was a student of natural history and medicine at the Universities of Berlin, Heidelberg, and Halle, at which last-named school he graduated as Ph.D. Having gone to Kiel in 1865, he was there appointed prosector in room of Dr. Hensen, who had just been elected Professor Extraordinary of Physiology. In the following year he passed successfully the examination for Doctor in Medicine, and thereafter qualified as *privat-docent*. In 1876 he was elected Professor Extraordinary of Anatomy, but still kept his favourite post of prosector, and laid the University of Keil under signal obligations by the skill and zeal with which he continued to attract *alumni* to the school. For twenty-one years his popularity never flagged, while the number of his pupils steadily rose.

Among his contributions to the literature of his special department may be mentioned his "Grundriss der Anatomie des Menschen" (Berlin 1879-81); and his "Anatomische Vorlesungen für Aerzte und ältere Studierende, Theil I.' (Berlin, 1884). Besides these works, he was a steady and esteemed contributor to the professional journals; while to a still more extended circle he was favourably known for the part he took in the Second German Expedition to the North Pole (1869-70), to the scientific report of which (1873) he contributed many valuable observations.

Medical News.

NAVAL MEDICAL SERVICE.—The following gentlemen who competed at the examination recently held at Burlington House for appointments as Surgeons in the Royal Navy have been granted commissions:—

	Marks.		Marks.
Bradley, James	3180	Woodwright, C. S.	2880
Hewlett, George	2975	O'Brien, Michael	2820
Waters, Geo. Alex.	2975	Shand, Jonathan	2790
Stott, Wm. G.	2900	Whitelegge, Wm. A. ...	2710

INDIAN MEDICAL SERVICE.—The following is a list of candidates for appointments in this Service who were successful at the competitive examination held at Burlington House on the 8th inst. and following days. Of the 59 candidates who competed for twenty-three appointments, 55 were reported qualified:—

	Marks.		Marks.
Roberts, A. E.	3360	Buchanan, W. J.	2960
Macwatt, R. C.	3165	Close, J. K., M.D.	2950
Nott, A. H.	3160	Dewes, F. J.	2930
Lamont, J. C.	3145	Brabazon, H. M.	2910
Woodwright, W. H. E. ...	3120	Griffith, J. H.	2895
Coleman, A.	3060	Ingham, W. H. M.	2890
White, W. W.	3050	Pinta, J. O.	2890
Maynard, F. P.	3045	Holt, J.	2880
Lane, D. T.	3020	Jones, J. L. T.	2875

COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND.—The undernamed have passed the Final Examination under the Conjoint Examining Board:—

J. Abbott, A. Austin, B. Beamish, A. Bewley, T. Cohen, S. Cox, W. Cremin, H. Cummings, R. Flynn, E. Frazer, E. Glynn, W. Graves, J. Harty, R. Hewitt, R. Jones, P. Keane, C. Lyons, J. Mc Naboe, J. Mannix, J. Moore, R. Pennyfeather, M. Shanley, W. T. Steele, and J. Stewart.

THE annual Hospital Sunday collections on behalf of the Worthing Infirmary were made on the 14th inst.

Two deaths from heat occurred in the City of London on the 22nd inst.

A SUM of about £600 has been received for the Walter Moxon Memorial. The subscription list closes on the 31st inst.

THE Edinburgh Medical Missionary Society received as a year its largest income, and started this year with its largest number of students—twenty-three,—of whom six are missionaries' sons, one of them the grandson of Dr. Moffat.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The name of Mr. A. Carter was omitted from the list of candidates, recently published by us, who have passed the final examination for the licence of this College.

THE annual meeting of the subscribers to the North Devon Infirmary was held at Barnstaple on the 16th inst., when satisfactory financial and general reports were presented by the committee and adopted.

SUPERANNUATION ALLOWANCE.—Dr. Charles P. Stevens, late medical officer for the Biggleswade Union, has, after forty-five years' service, been granted a retiring allowance of £25 per annum.

SPECIAL efforts are at present being made by the Health Department of the city of New York, to prevent, as far as possible, the excessive overcrowding of tenement houses, which is the source of so much disease and mortality.

THE 21st inst. was the day set apart by the Barnsley Hospital Sunday Committee, which of late years has provided by collections and otherwise half the funds for the Beckett Hospital, for the annual festival. The proceedings were largely attended.

AT a special general meeting of the governors of the Sheffield Infirmary, held on the 19th inst., it was unanimously decided to appoint two additional surgeons and two assistant physicians, the senior staff of physicians being reduced from three to two.

NEARLY all the guests, twenty in number, at a wedding party recently held at Winsford, Cheshire, have been attacked with illness, one of the cases proving fatal. An analysis is being made of the contents of a dish of mutton suspected to contain poison.

NEW DRAINAGE WORKS AT ACTON.—The main drainage works at Acton, constructed at a cost of £75,000, were formally opened on the 25th inst. The process of clarification adopted is that which dispenses with the use of lime as a precipitant and employs in its place magnetic ferrous carbon.

THE FRENCH COMMISSION ON FIRES IN THEATRES.—M. Emile Trélat has reported on behalf of the French subcommission on fires in theatres strongly in favour of the use of chemicals rendering the stage and all its contents uninflammable, stating that the expense will not be so great as is imagined, and should fall on theatre-goers, who cannot grudge an extra charge for safety.

UNIVERSITY OF CAMBRIDGE.—From the Calendar of this University, which has just been issued, it appears that the total number of members of the University whose names are retained on the College books, is 12,546. Of these 6527 are members of the Senate—that is, have taken the degree of M.A.; 3040 are graduates under the status of M.A., and 2979 are undergraduates. The total number of matriculations during the past academical year was 1012, while in the preceding year the number was 950, showing an increase of 62.

THE Government of Peru has invited the Republics of Central and South America to co-operate in a Sanitary Congress to be held in Lima on Nov. 1st.

THE MIDDLESEX HOSPITAL.—A great demonstration of temperance and friendly societies was held on the 21st inst., in aid of the funds of the Middlesex Hospital. The institution has been closed since the beginning of July for cleansing and repairs, and is announced to be reopened in the course of a few weeks.

BEQUESTS.—The late Lady Caroline Emily Nevill has bequeathed £100 each to the Brompton Hospital for Consumption, the Royal Hospital for Incurables, and the Maidstone Infirmary.—The late Mr. John Floyer of West Stafford, near Dorchester, has bequeathed £100 to the County Hospital, Dorchester.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—The following have been elected officers of this Society for the current year:—President: Mr. F. W. Salmann. Vice-presidents: Dr. W. Withers Moore, and Mr. E. Noble Edwards. Treasurer: Mr. Hodgson. Hon. Secretaries: Mr. Cresswell Baber and Dr. Whittle. Honorary Librarian: Dr. Gasquet.

THE BRITISH ASSOCIATION.—At the meeting of the members of this Association, to be held at Manchester next week, amongst other papers to be read are one by Professor Schäfer, on the Present Aspect of the Cell Theory; and one by Professor Ray Lankester, on the question, Are acquired Characters Hereditary? The guarantee fund for the meeting exceeds £10,000.

RABIES IN RICHMOND PARK.—It has been reported to the Richmond bench of magistrates by the official veterinary inspector of the district that during the past week no fewer than nine deer suffering from rabies in Richmond Park have been slaughtered. This is the largest number yet reported in one single week. Nearly the whole of the herd of deer, among which the outbreak occurred some months ago, have now been exterminated.

PROPOSED SMALL-POX HOSPITAL FOR SHEFFIELD.—At a specially convened meeting of the committee of the Sheffield Borough Hospital on the 19th inst., it was decided that the accommodation for small-pox patients at that institution is not sufficient during the prevalence which now prevails, and that it is desirable that more should be provided. This may almost be regarded as the first step towards the establishing of a small-pox hospital outside the town.

POISONOUS FISH.—In the exhibition recently opened at Havre there is an interesting collection of specimens of poisonous fishes. Some are poisonous when eaten; others are merely venomous. Among the first are many Sparoids, a Tetrodon, and many *Clupea*, which are abundant near the Cape of Good Hope. In the Japan Sea is found a very peculiar Tetrodon, which is sometimes used as a means of suicide. It brings on sensations like those produced by morphia, and then death.

LONGEVITY IN ALGERIA.—A list of aged people living in Algeria has just been published, according to which there are now in Blidah an Arab 108 years old and a Moorish woman aged 110. At Chercell, also, there is a Moorish woman who is 102 years old, and whose brother died a short time ago at the age of 110. Then, at Alger, there are two Frenchmen, each 100; a Spaniard, 99; two Poles, each 98; and two Arab-Jews, both of whom count their hundred winters.

THE REPORTED DEATH OF MR. H. M. STANLEY.—A letter has been received from Surgeon Thomas H. Parke, A.M.S., who is the only medical man accompanying Mr. Stanley's expedition for the relief of Emin Pacha, dated Aruwimi River, June 20th, 1887, stating that Mr. Stanley and the European officers accompanying him are all quite well. Mr. Stanley was then forming an entrenched camp, two days' journey up the river, whence, after eight days for arrangements, they were to make a forced march of 400 miles of difficult, unexplored country to Wadelai, to meet Emin Pacha. This, of course, allays anxiety about the reported death of Mr. Stanley, announced by a telegram dated June 17th last.

MEDICAL NOTES IN PARLIAMENT.

Rabies in Windsor Park.

In the House of Commons on the 22nd inst., Mr. Labouchere asked whether the newly-issued regulation that all dogs taken into Windsor Park were to be "muzzled or led" was issued with a view to protect the game, or in consequence of an epidemic among the deer, and, if the latter, how many deer had died or been attacked with rabies; and under whose authority and under what Act of Parliament the Ranger or Deputy Ranger was empowered to prevent the free use of the park and forest roads to the public and their dogs.—Mr. Jackson, in reply, stated that owing to the outbreak of rabies among the deer in Richmond Park, resulting in the loss of a large number, it was considered advisable to take steps to guard against any similar outbreak in Windsor Park, and with that view the notice referred to was issued by his Royal Highness the Ranger. No deer had died in Windsor Park of rabies, but it was known that at least twelve deer were worried and killed by dogs there before the notice referred to was issued. The Ranger was appointed by Her Majesty and the Deputy Ranger by the Ranger. They derive their powers by virtue of their appointments, and not under any Act of Parliament or from the Commissioners of Woods.

Vaccination.

On the 23rd inst., in reply to Mr. Picton, Mr. Ritchie stated that no report was made to the Local Government Board by Mr. Hutchinson about the year 1877 with reference to patients stated to be suffering from syphilis through vaccination, and so far as the Board are aware no report was made by him at the request of Dr. Seaton. The Board believe, however, that a report was made in 1871 to the Royal Medical and Chirurgical Society by Mr. Hutchinson, but that report, as stated by him before the Vaccination Committee in 1871, was made on the application of the medical man in attendance on the cases, and not of Dr. Seaton. The Board are aware of the cases of vaccino-syphilis which are referred to in Mr. Hutchinson's publication. Three out of the six cases referred to in the question as a "long series" related to single cases, and the most recent of any of the occurrences related took place between ten and eleven years ago. The Board have the authority of Mr. Hutchinson for saying that though he has been diligently on the look out for similar cases during the ten years' interval he has failed to meet with any. In his recent work, published this year, on the subject, Mr. Hutchinson says:—"There certainly cannot be any difficulty under ordinary circumstances in procuring vaccinifere which are absolutely free from risk." Mr. Hutchinson's experience was in these respects entirely confirmatory of that of the Board, which is to the effect that although three-quarters of a million of children have been vaccinated annually for many years past not a case of the communication of the disease in question by vaccination has come under their observation.

The Coroners Bill.

Mr. W. H. Smith, replying to Mr. Bryce, said the Coroners Bill was a measure to consolidate the existing law, and bring it into harmony with the practice. It would undoubtedly be a misfortune if the labour which had been expended on this Bill should be thrown away, and the Government would adopt the suggestion of the hon. Member not to drop the Bill, in the hope that as it was beneficial to the public, and involved no political question of any kind, it might be passed this session.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADKINS, GEORGE, L.R.C.P. Lond., M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health to the Plympton St. Mary Union Rural Sanitary Authority, till July 25th, 1890.

ANDERSON, JAMES KEITH, M.D.Ed., L.R.C.S.Ed., has been appointed Medical Attendant to the Arbroath Infirmary.

ATKINSON, G. ARMSTRONG, M.D.Ed., has been appointed Honorary Physician to the Newcastle-upon-Tyne Dispensary, vice Lucius Holland, M.D.Aber., deceased.

BARRON, HUNTER, M.D., M.R.C.S., has been appointed Surgeon to the S Division, Metropolitan Police (Finchley Station), vice J. Hochee, M.R.C.S., resigned.

BREDIN, HOWARD A., M.R.C.S., L.S.A., has been appointed Medical Officer for the Eastham District of the Wirral Union.

BROWNE, J. W., M.D.Q.U.I., M.R.C.S., has been reappointed Attending Surgeon to the Belfast Royal Hospital.

BYERS, JOHN W., M.D., M.Ch. Q.U.I., has been reappointed Attending Physician for Diseases of Women to the Belfast Royal Hospital.

COLLIER, JOSEPH, M.B., B.S., F.R.C.S.Eng., has been appointed Assistant Surgeon to the General Hospital for Sick Children, Pendlebury, Manchester.

FITZGERALD, JOHN R., L.R.C.S.I., has been appointed Medical Officer for the Stotfold District of the Biggleswade Union.

GWYNNE-HUGHES D., L.R.C.P., L.R.C.S.Ed., has been appointed Resident Medical Officer to the Sydney Hospital, vice R. Westrum, M.D., resigned.

KINNEIR, FRANCIS W. H., M.R.C.S., L.S.A., has been appointed Medical Officer for the Fourth District of the Horsham Union.

LAING, DAVID, M.D., C.M.Edin., has been appointed Attending Surgeon to the Arbroath Infirmary.

LINDSAY, JAMES ALEX., M.D., M.Ch. Roy. Univ. Irel., has been reappointed Assistant Physician (extern department) to the Belfast Royal Hospital.

MONRO, WILLIAM, M.D.St.And., L.R.C.S.Ed., has been reappointed Surgeon to the Arbroath Infirmary.

MORRIS, COLIN DWIGHT, L.R.C.P.Lond., M.R.C.S., L.S.A., has been appointed Surgeon to the Bedfont Division of the Metropolitan Police, Medical Officer to the Fulham Provident Dispensary, and Surgeon to the Bedfont and Hatton Mutual Benefit Societies.

NELSON, JOSEPH, M.D.Q.U.I., L.R.C.S.I., has been reappointed Attending Surgeon to the Belfast Royal Hospital.

O'CONOR, JOHN, M.B., B.Ch. T.C.D., has been elected House-Surgeon to the Royal Portsmouth, Portsea, and Gosport Hospital, vice J. P. Williams Freeman, M.B., resigned.

POGSON, W., F.R.C.S., L.R.C.P.Ed., has been reappointed Medical Officer of Health for the Leeds Rural Sanitary Authority.

ROSS, RICHARD, M.D.St.And., L.R.C.S.I., has been reappointed Attending Physician to the Belfast Royal Hospital.

RUSSELL, JOHN, M.B., C.M.Aber., has been appointed Medical Attendant to the Arbroath Infirmary.

SUMPTER, B. G., M.B.Dunelm, M.R.C.S., has been appointed House-Surgeon to the West Norfolk and Lynn Hospital, King's Lynn.

VALPY, CHAS. EDWARD, B.A., Merton College, Oxford, M.R.C.S., has been appointed Senior House-Surgeon to the Cancer Hospital, Fulham, vice H. G. Shaw, resigned.

WILLIAMS, JOHN HENRY, M.R.C.S., L.S.A., has been appointed Medical Officer of Health for the Llanybyther Division of the Lampeter Rural Sanitary District, vice Davies, resigned.

WINN, JOHN, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer of Health for the Fylde Rural Sanitary District, Lancashire.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

ASHFORD FRIENDLY SOCIETIES AND PUBLIC MEDICAL ASSOCIATION.—Out-door Assistant. Salary £100 per annum.

BIRMINGHAM GENERAL HOSPITAL.—House Governor. Salary £300 a year, with board and apartments.

DENBIGHSHIRE INFIRMARY, Denbigh.—House-Surgeon. Salary to commence at £85 per annum, with board, residence, and washing in the house.

HOSPITAL FOR WOMEN, Soho-square, W.—Two Out-patient Clinical Assistants. Fee for course of three months 5 guineas.

JARROW-ON-TYNE MEMORIAL HOSPITAL.—House-Surgeon. Salary to commence at £130 per annum, with board and residence.

MAIDSTONE UNION.—District Medical Officer and Public Vaccinator. Salary as Medical Officer, exclusive of fees, £60 per annum.

MANCHESTER ROYAL INFIRMARY.—Resident Surgical Officer. Salary £150 per annum, with board and residence.

ROYAL BERKS HOSPITAL, Reading.—Assistant House-Surgeon. Board and lodging, but no salary.

ST. PETER'S HOSPITAL FOR STONE, Henrietta-street, Covent-garden.—House-Surgeon. Honorarium (for six months) 25 guineas, board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

EVANS.—On the 23rd inst., at Denmark Lodge, Clapham-common, the wife of Lewis Evans, L.F.P.S.Glas., L.R.C.P.Ed., of a daughter.

HENDERSON.—On the 18th inst., at 6, Hampstead-lane, Highgate, the wife of A. Milne Henderson, M.D., of a son.

OWEN.—On the 24th inst., at Seymour-street, Portman-square, the wife of Edmund Owen, F.R.C.S., of a daughter.

STEER.—On the 12th inst., at Sportsman's Hall, Stewart Town, Jamaica, the wife of A. W. Thorburn Steer, M.R.C.S., L.R.C.P.Lond., of a daughter.

VERRALL.—On the 17th inst., at Montpellier-road, Brighton, the wife of T. Jenner Verrall, M.R.C.S., L.R.C.P., of a daughter.

WILKIE.—On the 19th inst., at Simla, the wife of David Wilkie, M.B., C.M.Glas., I.M.S., of a daughter.

MARRIAGES.

FAYLE—LEECH.—On the 20th inst., at Long Ashton Church, Robert J. L. Fayle, L.K.Q.C.P.I., L.R.C.S.I., Surgeon, Army Medical Staff, Secunderabad, India, to Mary, second daughter of Joseph Leech, of Leigh Woods, Clifton.

GILBERT—WOODS.—On the 18th inst., at St. Stephen's, Twickenham, Clarence Edwin Lloyd Gilbert, L.K.Q.C.P.I., M.R.C.S., Indian Medical Service, to Isabella Lilian, second daughter of Lieut.-Col. J. A. Woods, late Royal Dublin Fusiliers.

KERSHAW.—On the 16th inst., at the West Derby Parish Church, Liverpool, by the Rev. R. J. Rolfe, John Cawthron Kershaw, M.R.C.S.B., L.R.C.P.Ed., of New Wortley, Leeds, to Jane, only daughter of W. A. Punshon, Esq., of Liverpool. (No cards.)

DEATH.

TREND.—On the 13th inst., at Potton, Beds (very suddenly), Henry Gristock Trend, L.R.C.P., late of Highbury, aged 55.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE STUDENTS' NUMBER OF "THE LANCET" will be published on Saturday next, Sept. 3rd. Those gentlemen holding official situations connected with medical institutions in the United Kingdom who have not yet forwarded the necessary information to our Office for publication in that number are earnestly requested to send it *without the delay of a single post.*

BACTERIA IN HAIL.

W. J. C. (Birmingham).—Prof. L. Maggi of Pavia. Following up the researches of Bischoff and Fränkel, who have investigated bacterial life as occurring in natural water and ice, the Italian physiologist has found the same organisms in hail. He has classified these as belonging to the three orders of sphero-bacteria, micro-bacteria, and desmo-bacteria, the first being the more numerous.

C. M.—The idea is not new.

A SINGULAR CASE OF ECTOPIA OF THE THORACIC AND ABDOMINAL VISCERA.

To the Editors of THE LANCET.

SIRS,—The following case is, I think, worth recording:—

Mrs. A——, aged thirty-six, fourth confinement, labour commenced at 10 A.M. on July 23rd. I was sent for at 3 P.M. On arrival I found a head presenting in the first position; labour progressed rapidly, and the child was born alive at 4.15 P.M. I then found that there was a second child in utero, having also head presenting; the pains came on rapidly, and the child was born alive two minutes after the first, followed almost immediately by the placentæ. The second child presented a very peculiar malformation. The thorax and abdomen were open from the neck to the pelvis, and on each side as far as midway between the sternum and spinal column; the sternum was absent, the lungs and heart were outside the chest, the apex of the heart being directed laterally to the right; the aortic arch gave off four branches, two carotid and two subclavian; the abdominal organs were all lying outside the body. The child lived three hours and a half, during which time the pulsations of the heart could be counted; it never cried, and was somewhat smaller than the first. Both were female children.

I am, Sirs, yours truly,

Aug. 20th, 1887. J. MCAVOY, M.D.

CINCHONA CULTURE IN RÉUNION.

AT the present time, owing mainly to losses on coffee and sugar, planters in most British tropical and sub-tropical colonies—especially in Ceylon and the West Indies—are turning their attention to cinchona cultivation. It may, therefore, be well to call attention to the process followed in Réunion, as described by Mr. St. John in his last consular report from that island. The difficulty of removing the bark from the tree appears to have received a more practical solution there than either in Java or the British colonies. In Réunion the plantations are made in forests at a height of about 4000 ft. At this altitude there exist no high trees, but merely brushwood. Parallel alleys from five to six feet wide are made, and, as far as practicable, in spots sheltered from the winds. These alleys are separated by a range of brushwood 10 ft. thick on each side, which serves to protect the young cinchona plants against the violent winds so common in Réunion. The alleys being made, holes are dug at a distance of 15 ft. apart, 20 in. in diameter, and of the same depth. These holes are then filled with the earth which has been dug up, to which some mould is added. This mixture forms at the surface of the soil a convexity, in the middle of which the young cinchona plant is placed and experiences no difficulty in its growth. When it has reached a height of 18 in. care must be taken to cut the roots of the adjoining brushwood which may have found their way into the space reserved for the cinchona. At the end of seven or eight years plants will have reached a diameter of 3½ in., and are ready to be worked. The process then pursued is this:—Towards the month of October, when the sap resumes its upward movement and the bark is more easily detached, the plants are cut at about two inches from the ground. The bark is then taken off and put in the sun to dry. From the stump that remains there soon spring a great number of young shoots, which, when they have in their turn attained a certain size, it is necessary to lop off, only leaving a number of sprigs, which the stump is able to feed conveniently. These have a rapid growth, and at the end of another period of six or eight years a new crop is ready. In this way the cultivation of cinchona once planted can be continued almost indefinitely and at little expense. This is a far more economical method than that employed in Java, and the experiments in Réunion have hitherto proved very successful.

Nuntius.—A physician "of right," strictly speaking, is a member or associate of a college of physicians; but a medical graduate of a respected university in actual practice is certainly, in the best sense of the word, a physician, and entitled to be called such, or to call himself such.

Dr. Walters is referred to our annotation on page 1297 in the issue for June 25th of the present year.

Sufferer should consult his medical attendant.

HOW EXAMINATIONS ARE CONDUCTED.

To the Editors of THE LANCET.

SIRS,—At the last examination of the Royal College of Physicians I presented myself and was allotted a certain day for the *viva voce* in medicine, but two or three days later I received another card altering the date to one four days earlier. The examination being over, I am kept waiting till the very last, and then told "that the clerk had forgotten to acquaint the examiners with the fact that the date of my *viva voce* had been changed; but that they would write to me as soon as the examiners brought my medicine papers and reported on them. I go away to the country the next day to wait a week without hearing anything. I then telegraph to the Examination Hall, and have a reply sent to me, saying, "that I have 'passed,' but that if I wish to receive my diploma this time, I must come up to London at once and sign the book." This, of course, I refused to do, and then an affidavit form is sent me, which I fill up and get the diploma. But on returning to London I am met with condolences from my friends, both professional and non-professional, as my name has not appeared in the lists of passed candidates in the medical journals. I think it is most disgraceful that such laxity should exist, and it appears to be common, for a similar occurrence happened to me at the B.S. examination of Durham, when my name was crossed off as having failed when I had passed.

Hoping that the insertion of this letter will aid in preventing such occurrences, I am, Sirs, yours faithfully,

Belsize-square, N.W., Aug. 17th, 1887. F. W. EDRIDGE GREEN, M.B.

THE DUODENUM: A SYPHON TRAP.

To the Editors of THE LANCET.

SIRS,—Kindly permit me to ask the following questions through the medium of your valuable columns regarding Mr. Collier's original article on the above subject:—Is it possible, by taking into consideration the peristaltic action of the duodenum, that it will practically allow a volume of stagnant liquid within its calibre, as it is generally found empty in post-mortem examinations? How are we to account for the fetid gases which are driven upwards in the clinical phenomena called stercoraceous vomiting? I am, Sirs, yours faithfully,

Hucknall Huthwaite, Aug. 25th, 1887. D. G. EVANS.

Digitized by Google

LANGMORE DEFENCE FUND.

SINCE the publication of the fifth list of subscriptions in THE LANCET of June 11th, a donation of one guinea has been received from Dr. T. L. Rogers, Rainhill, Lancashire. The fund amounts to £168 5s. 6d., and cheques for £158 12s. 6d. have been forwarded by Mr. Eastes to Dr. J. Wreford Langmore. The balance (£9 13s.) is composed of four subscriptions (amounting to £8 8s.) promised but not yet paid to the honorary secretary of the fund, and of the expenditure (£1 5s.) incurred for postage, &c. As Dr. Langmore's expenses at the trial (which were allowed him by the judge, but which the plaintiff, being a person of small means, could not settle) amounted to more than £240, he still has to pay about £80 beyond the amount raised by the subscription. If any gentlemen desire to assist further in defraying this expense, the secretary of the fund, Mr. George Eastes, M.B., 69, Connaught-street, Hyde-park-square, London, W., is willing to receive their subscriptions, and forward them to Dr. Wreford Langmore.

Nemo.—It is obvious that we cannot be responsible for the good faith of all our advertisers.

Studeo has not enclosed his card.

"GAELIC MEDICINE."

To the Editors of THE LANCET.

SIRS,—With reference to the notice under this heading in your issue of the 6th inst., and dissenting entirely from your dictum that "impaired eyesight is a very common failing in the Irish recruit," I have pleasure in offering for your kind acceptance the following description of the "Leech in Ancient Ireland," as that is set forth in Dr. Sullivan's learned edition of Eugene O'Curry's "Manners and Customs of the Ancient Irish," vol. i., page 309. Describing the office and emoluments of this functionary, Dr. Sullivan says, that "he appears to have been respectable and eminently practical. The value of cleanliness, of water and fresh air as curative agents, appears to have been thoroughly appreciated [by him], for we are told that the Leech's house, in addition to having a stream of water flowing through it, should have four doors, in order, as the law says, that it may be perceived from all sides. Another object of the four doors was that it might have at least one of them always open, no matter from what point the wind blew, and thus ensure the proper ventilation of the sick chamber. The hot-air bath was used for the cure of rheumatism, which must have been very common, and it is probable that the remains of such baths, which are found here and there throughout the country, indicate the localities where Leechs' houses formerly existed. A physician had (our author says) certain rights over water, he had not only the right, but was in fact obliged to build his house over a running stream, not over a spring. Among the early Irish the Liag or Leech sometimes treated his patient in his own house; he supplied not only medical advice, but medicines and hospital accommodation also. When a man was accidentally or maliciously wounded, he was taken to the house of the Leech, who examined his wounds and gave a certificate to their character, upon which depended the legal liabilities of the person who defended them. If the Leech considered the cure probable, he gave security for the proper treatment of the patient and received in turn security for his fees. These were, of course, paid in kind, as in cows, presents, &c. Thus, four cows and a heifer were paid for the cure of the maim from a king or from those who are of equal value with him; three cows for a maim, for which the fine of infliction would be three cows; a cow and a heifer for a wound, for which six calves are the fine of infliction; a cow and eighteen screpalls (alms or presents) for a wound for which seven calves were the fine of infliction." As an instance of the universality of the practice of cremation, I may be allowed to quote as follows from this same source:—"The numerous urns containing burnt bones, found in the Irish tumuli, prove that at some period cremation of the dead was practised in Ireland." So were "marrow baths" used, at times, by these same Leeches as tonics, and to show the spirit—the ever kindly and merciful spirit—that animated my much maligned and even now much misunderstood countrymen, I may be permitted to add here, in this connexion, that though the Druids—in other words, the medicine-men of Gaul and Britain—sacrificed a man for the recovery of those who were afflicted with a dangerous disease, there is no evidence that the Irish Druids ever did offer or recommend the offering of human sacrifices. I am, Sirs, your obedient servant,

Auriol-road, W., Aug. 21st, 1887. W. CURRAN.

PARALYSIS AFTER DELIVERY.

To the Editors of THE LANCET.

SIRS,—On May 11th I attended Mrs. H—— in confinement. It was a very difficult instrumental delivery, partly due to a pendulous abdomen. She informs me that each time she has required instruments. The recovery was good with the exception of a temporary paralysis of the muscles of the left leg, the patient being unable to walk without support for six weeks after the confinement, when she began rapidly to improve. I treated her with bromide of potassium and friction with counter-irritants. I must add there was slight puffiness of the ankle, and severe pain in the leg, with a sensation of pricking by pins and needles. Might I ask some of your readers to kindly inform me whether this is a common occurrence, and, if so, what is the etiology? I am, Sirs, yours truly,

August 22nd, 1887. VOLEL.

PILL PRESCRIPTIONS FOR MEDICINE CHESTS.

C. T. S. asks an opinion on a little pamphlet which he encloses, to be taken by any passer-by at the American Exhibition. Our opinion is that the name of any practising physician is better withheld from such commercial advertisements, which will not tend to increase public intelligence or the safety of invalids. Not that the prescriptions individually are bad prescriptions; but one man's medicine is another man's poison, and in disease so much depends on individual constitution and circumstances and so little guide is to be found in a particular symptom, that such prescriptions are an evil rather than a good. We decidedly disapprove of advertising sulphate of copper and opium as "anti-diarrhœtic or corrective pills," or opium and antimony, &c., as catarrhal or sudorific pills.

Mr. Fenton.—We have no such information. We doubt there being any, except from quacks.

Inquirer.—The agents are Messrs. Barron and Wilson, 7, King William-street, West Strand, London, W.C.

SWEATING OF THE FEET.

To the Editors of THE LANCET.

SIRS,—In your last issue there is a letter from Dr. Richardson of Newhaven, in which he recommends soda for sweating of the feet, which has nearly always a very offensive smell. He also states that there is no specific for this complaint. Now it is well known that borax is a specific for it. I think I must have used it for ten years, and cured numbers of cases by it. I use three drachms of borate of soda to eight ounces of water, and tell the patient to bathe the feet in warm water, and apply the lotion with a sponge every night on going to bed.

I am, Sirs, yours truly,

Clifford-street, W., Aug. 25th, 1887. G. TAYLOR, M.D.

To the Editors of THE LANCET.

SIRS,—Inasmuch as the treatment of sweating feet seems to remain a vexed question, perhaps the result of a little personal experience may not come amiss. For several years I was a martyr to the complaint, trying fairly all the remedies I could hear of, nothing doing any good, but, if anything, becoming worse, until at last I was told that it had grown an established function of the body, and could not be stopped with impunity. However, I was one day recommended salicylic acid, two parts, and burnt alum, three parts, mixed together and well dusted between the toes and upon the feet, after washing them in warm water, to be repeated as often as necessary. At first I did it nightly, but soon learned that it was not necessary to do it so often; then once a week was sufficient, and then not at all. Since, I have tried it many times, and always with success, upon others, and would advise anyone else to do likewise. Needless to add that it improves the comfort of the operation to tie a folded kerchief over the nose and mouth during its performance.

I am, Sirs, yours faithfully,

Aug. 23rd, 1887. GOOD.

Young Student.—The question cannot be answered in the form it is put, for it is a series of questions. We doubt whether the method mentioned is particularly efficacious.

Mr. Masters (Weston-super-Mare).—We can only suggest advertising.

LONDON FIRES.

To the Editors of THE LANCET.

SIRS,—With reference to your annotation at page 336, if you think fit to place before your readers for criticism a scheme to prevent and to extinguish fires that has occupied my thoughts for many years, I shall feel obliged. In rebuilding premises, now destroyed or erecting new buildings, let the walls of each room be hollow with a layer of perforated bricks placed every three or four feet and in connexion with a properly constructed chamber, the size of which must be regulated according to the extent of the building or buildings, the pipe or pipes leading from the chamber to the building being each capable of ready closure or opening. The chamber itself must always be full of chalk and water, a separate reservoir of hydrochloric acid being so arranged that it may be poured into the chalk and water at a moment's notice. By the aid of a steam engine the gas, mixed with air, robbed of its oxygen by passage over incandescent coke, is then pumped into the burning building, through the hollow walls, or by proper pipes if the walls be not hollow; separate hoses leading from the reservoir of carbonic acid gas being provided for the firemen's use, who, protected by Fleuss's helmet or similar apparatus, can work unharmed in the vitiated atmosphere. Were the men encased in perforated leather dresses so arranged that carbonic acid gas could be forcibly ejected through the perforations, they could walk into the fire unharmed. Had some modification of this scheme been at hand on board the steamship *City of Montreal* the terrible fire would have been extinguished in a few minutes. Fires could thus be extinguished without damage to goods around; and even if water be needed, that charged with carbonic acid gas would be infinitely more effectual.

I may say that on the occasion of each great fire a trial of the above scheme has been in vain solicited.

I am, Sirs, yours truly,

Boundary-road, N.W., Aug. 1887. RICHARD NEALE, M.D. Lond.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 3, 1887.

ADDRESS TO MEDICAL STUDENTS.

IT becomes our duty to-day to give our annual address to those engaged in the studies necessary for obtaining admission to the profession of medicine. On former occasions we have dwelt upon the choice of a medical school, the selection of class-books, and the general *technique* of the professional curriculum. To-day we propose to make a few observations on the spirit in which medical study should be conducted, and then to pass on to the consideration of the life-work for which that study is designed to be the fitting preparation. We speak not alone to those who are students in the strict sense of the term. In a very real sense we are all, young and old, medical students; all engaged in the study of morbid processes, and the means employed for their relief; all ready to learn from anyone wiser or more experienced than ourselves; all conscious of the limitations of our knowledge, and the vast field of research still ungarnered, and already white unto the harvest. The physician or surgeon ceases to be a medical student only when his pulse ceases to play, and he rests for ever from his labours.

Education, in the genuine and higher signification of the term, consists not so much in the acquisition of knowledge as in the development of faculty; not in the accumulation of facts, but rather in the recognition of principles. The medical student cannot too early recognise that the main end of his professional training is not to fill his memory with descriptions of disease and routine rules of treatment, but to fit him to observe for himself and to reason accurately upon the facts of observation. The descriptions and classifications adopted in class-books, often excellent in their way, are apt to mislead the beginner regarding the fixity of nature and the homogeneity of disease. Probably there never yet were two cases of disease precisely similar in all details, and the student will strive in vain to find in the widest fields of observation the stereotyped cases which a careless reading of his text-books might lead him to expect. Nature, though ever true to herself, varies within limits that are practically infinite. "All things are in flux," said the ancient poet, and nowhere is the dictum truer than in the realm of disease. Hence the fatuity of "cram" in medical education; hence the supreme necessity that the medical student should early accustom himself to allow for the uncertainty introduced by the variability of pathogenic influence and of individual idiosyncrasy. Many practitioners undoubtedly reason hastily from one case to another. A drug has benefited one patient, therefore it will benefit another; a remedy has been useful in one case of a certain malady, therefore it will be useful in another case of the same malady. Such reasoning is by no means rare, but it is the reasoning of a quack and an empiric, and not of a man of science.

Towards the formation of the habit of exact observation nothing can more certainly conduce than the resolute study of anatomy. This subject is undoubtedly distasteful to many minds, some of them of the higher order, but the student who neglects it is dogged by a remorseless Nemesis throughout his entire professional career. An exact knowledge of the structure of the body is not only indispensable for the physician, and *à fortiori* for the surgeon; but, as we have implied, the process by which alone that knowledge can be acquired is a wholesome and indispensable discipline. Let the student accustom himself to regard the human body as a wonderful and complicated piece of mechanism, of which he has to discover and remember all the props and stays, all the wires and tubes and springs. Regarded thus, anatomy can no longer repel as a mere collection of dry and disconnected facts. Rather will it become a study of absorbing interest, in which every step securely taken opens up the road of further advance.

Just as anatomy deserves to hold the first place in the earlier stages of the medical curriculum because of its educating influence, so in the concluding stages must priority of importance be accorded to clinical study. The student who is a zealous anatomist in the first two years of his course, and a zealous observer in the hospital wards during the remaining two, is on the high road to professional usefulness and possibly eminence. Hospital work is the real preparation for practice, and to it all other studies are subsidiary and preparatory. In the wards of a hospital the student not only learns to recognise the characteristic features of disease and the general outlines of treatment, but there also his mind, with regard to professional knowledge, receives its first and most indelible impressions. A vivid clinical lecture leaves its mark for aye; a chance word of a trusted teacher becomes an axiom for life; a case presenting striking features and conveying serious lessons remains a landmark and sign-post during all succeeding years. Hence hospital experience more than all else makes the student what he will be for life; hence the well-known fact that certain hospitals impress upon all their *alumni* a certain mental tone and colour which constitute their tradition; hence the paramount duty that hospital instruction should be genuine, thorough, honest, free from bigotry, prejudice, or partiality. If statesmen and soldiers make history, the hospital physician or surgeon does much to make human life, and it is fitting that he should recognise the full measure of his responsibility.

We would advise the young student to begin his hospital work with a determination to use his own senses and intellect for the discovery of knowledge. It is impossible to acquire any genuine acquaintance with disease through the medium of books alone. The student must handle diseased structures, watch morbid processes, call in the aid of sight, touch, hearing, and smell for the discovery of deranged function. Each sense must be on the alert to receive impressions, while the brain is constantly at work in their interpretation. Of course, undirected and undisciplined observation will accomplish little. The student, in proportion to his inexperience, will need the constant help and supervision of his teachers and a frequent reference to his text-books; but, we repeat, personal observation is the only secure foundation of a really permanent and fruitful knowledge of disease.

Digitized by Google

The student need not be surprised or disheartened if his first feeling on entering the wards of a large hospital is one of simple bewilderment. Many distinguished men have described the sensation of despair which palsied their minds on first attempting to find order in the apparently inextricable chaos of disease. But this is an evanescent sentiment. Each day's experience, if honestly acquired and diligently tabulated, tends to clearness of vision and fixity of idea, and becomes the starting-point for further progress. By degrees the chaotic mass of morbid material takes shape and colour, and the apparent "wilderness of single instances," begins to acknowledge the principle of order and the rule of law. At this point another and more subtle danger needs to be shunned—namely, the danger of rash and hasty generalisation. The student, in his early delight at discovering order in apparent disorder, is apt to reason too precipitately from individual phenomena to general laws. Because a certain consequent follows a certain antecedent in one, two, three, or a dozen instances, he is liable to conclude that the causal relation is invariable, and thus to fall into the error known to logicians as the "fallacy of simple enumeration." Thus, to take a familiar instance—Does arsenic cure chorea? The student sees the drug given in this disease perhaps a dozen times; and let us suppose that recovery in each case results. He is most apt to conclude that cause and effect are here self-evident, especially if so informed authoritatively by his teacher. He does not readily reflect that the patients might conceivably have recovered under a quite different line of treatment, or that while his twelve cases recovered a thirteenth case might die. Every case of apparent cause and effect is entitled to be kept in memory and accorded its due weight, but it requires a multitude of such cases even to raise a presumption of a general law.

We would counsel the young student to attend diligently to the physiognomy of disease. It is by so doing that the trained hospital nurse acquires most of her knowledge, which is often surprisingly accurate, while at other times it is hardly less remarkably faulty. The eye alone can often go far towards establishing an exact diagnosis. Apart from such obvious cases as skin diseases, jaundice, anæmia, &c., in which simple inspection enables us to form a fairly accurate opinion, there are multitudes of other cases in which the aspect of the patient conveys information of great value. The flushed face, anxious expression, and suppressed breathing of a patient in the first agony of acute pleurisy; the orthopnœa, dusky hue, and throbbing arteries of a patient with advanced heart disease; the malar flush, sunken cheeks, and glittering eye of the dying consumptive,—all these and innumerable other cases carry to the trained eye their own interpretation, written only too plainly upon them. The aspect of a patient is valuable not only for diagnosis, but also for prognosis. The subtle changes from day to day, making either for life or death, may be too fine for detection by stethoscope or thermometer, but be visible to the experienced eye. The approach of the end is not seldom heralded by changes which the physician could hardly describe, but which he sees and reads with ease and confidence.

We will not stay to dwell upon the other features of clinical study to which attention might be directed, such as the importance for the student of persevering through the necessary drudgery of case-taking, the necessity of acquiring readiness and facility with such instruments of precision as the ophthalmoscope and laryngoscope, the duty of studying human nature as well as disease, and of remembering that the physician and surgeon deal not with inanimate things, but with beings responsive to sympathy and often oppressed by many sorrows. One word only we will add on this subject. Let the student be on his guard against too readily adopting the prevalent scepticism regarding the effect of remedies and the value of medical treatment. No doubt, the efficacy of drugs is receiving a severe sifting. We no longer regard medicines as potent spells to conjure with, and the present danger is rather lest the really immense influence of drugs over healthy and morbid function should be ignored. The student should early realise that, when all is said, success in treatment is the only justification for the existence of an art of medicine. All our minute pathology and refined diagnosis are of small value, except in so far as they enable us to prolong life or palliate suffering. The young student who begins with undue scepticism in therapeutics (a scepticism which is the less justifiable because it consists at bottom in disbelief in the value of remedies which have not yet received a thorough and patient trial) will be apt to drift into carelessness in diagnosis, and when this point is reached the practitioner is in the melancholy plight of living by the promulgation of a creed in which he himself is a secret disbeliever. There is nothing to be more desired for the student of medicine than that he should carry away from his hospital training a just and well-balanced judgment regarding both the resources and the limitations of his art, neither on the one hand scoffing at the value of doctrines established by the patient labour of long generations of great men, nor, on the other hand, clinging to antiquated superstitions, and practising with the blind and unintelligent faith of the empiric and the quack.

We pass on to make a few observations on the medical career on which many of our readers have entered, and to which others are looking forward with hope and expectation. If we could credit the vaticinations of professional Cassandras, the medical profession has fallen upon evil days. Our correspondence columns are often occupied with complaints regarding overcrowding, excessive competition, low remuneration, abuse of charities, &c.; and we do not doubt that such complaints have a certain justification. The stress and strain of the nineteenth century cannot be expected to leave any professional sanctuary free from invasion; we are sharing in the altered conditions of modern life, and it is for us to consider whether changed circumstances do not call for changed methods. The remedy is beyond question in our own hands. The public take from us their cue in their estimation of professional services, and are amenable to influences which it is in our power to exert. Without professing to consider remedies in detail, we think it is clear wherein much of the mischief consists. We need among ourselves a higher estimate of the dignity of our profession, and of the value of the services which it is in our power to render; a more scrupulous honour in shunning every suspicion of sacrificing the interest of a brother practitioner to our own advantage; a self-respect that can endure

Digitized by Google

poverty if necessary, but which will not tolerate either puffery or chicanery; and, lastly, a just estimate of our own rights, and a firm insistence upon them at the hands of the public. There can be no doubt that we suffer much and undeservedly from the abuse of medical charity. No one can value more highly than we that priceless heirloom of our profession—the principle that the suffering poor can command our services even if they come empty-handed; but the public need to be reminded again and again that if a man or woman who can afford to pay accepts gratuitous medical advice, or abuses the beneficence of our charitable institutions, he or she is guilty both of a meanness and a dishonesty. We should be sorry to see the commercial spirit prevail extensively among the profession, and we prefer the old notion that a medical fee is an honorarium, and not a quittance; but we must take human nature as we find it, and recognise that men, as a rule, value a thing just in proportion to the cost or effort of obtaining it, and that if they can get medical advice for nothing they are most apt to rate its value accordingly. We think "club practice" is being grievously abused, and might well call for attention at the hands of the licensing bodies. Again and again cases have been recorded in our columns of medical men giving their services in this line of practice at an average rate of less than a shilling per visit, medicine included. Now, *pace* CARLYLE, the people of this country are not "mostly fools," and egregious fools they would be to expect really efficient and honest medical service at this miserable rate. Let the public understand that if they want skilled attendance, and the bringing to bear for their relief the results of elaborate training and long experience, they must pay for them. They are wise enough to realise, if the matter be properly explained, that they cannot expect the benefits of a learned profession at a rate less than that paid to the carpenter for putting a broken chair to rights or to the plumber for inspecting the drains.

It is well, however, to remember that, on the whole, few careers hold out a more assured prospect of competence to character, industry, and perseverance than does that of a medical man. If the great prizes of the profession are few, the blanks are also few. The medical man who combines fair professional accomplishments with moderate talent and sound moral instincts rarely fails of attaining a reasonable competence, and a social position which, with certain inevitable drawbacks, has some very real compensations. It is no trifling inconvenience to have no certain leisure, to be able to take a holiday only at the cost of possible annoyance and certain financial loss, to have over-pressure of work at one season and under-pressure at another, to be always "on duty," and never able wholly to forget the physician in the man. On the other hand, it is no small compensation to feel that the daily work is not a mere bread-winning, but a labour of charity and usefulness—an image, however faint, of the deeds of the Divine Healer during

> "those sinless years
> That breathed beneath the Syrian blue."

It is quite true that any man, whatever his avocation, who discharges his daily duty with industry and uprightness is in some sense a benefactor of his race; but of few men is this so undeniable as of the medical practitioner. It is, indeed, happily impossible for him ever to become wholly selfish, inasmuch as the vigorous exercise of his talents, which builds up his own fortune, also subserves the interests of his patients. He has the double incitement to strive after professional excellence—viz., his own advantage and the well-being of those who commit their lives into his keeping. It is the happy characteristic of the medical profession that these two objects—one selfish, the other unselfish—are not only not opposed, but are indissolubly linked together.

Medical life is, or is capable of being, an admirable school for the formation of character. Few, if any, careers so appeal to the entire man, to head and heart, to sense, intellect, and feeling. Men of action can find room for the play of faculty in the operations of surgery or the experiments of therapeutics and pharmacology; men of reflection can find illimitable material for thought in the ever-varying phenomena of disease and the wonderful aberrations of the disordered machinery of the human organism.

We think few men who have deliberately chosen the medical career and successfully surmounted the initial difficulties which beset all professions ever regret their choice. Here and there we meet a man soured by disappointment, broken down by the pressure of "club" or "Poor-law" practice, or dissatisfied with the limitations of a career which fortune has placed in some remote and solitary spot. But such cases are relatively rare, and the great body of the profession undoubtedly consists of fairly prosperous men, who have a cheery and sympathetic word for every patient, and whose hard work has not taken the flavour and charm out of their lives. On the other hand, the hard logic of statistics shows that medical life has more than an average share of hardship, and some dangers peculiar to itself. The mortality rates of the three learned professions—Divinity, Law, and Medicine—are respectively 15, 20, and 25 per 1000; and if we take the period of active professional life, between the ages of twenty-five and sixty-five, we find that the death-rate among doctors is half as much again as among lawyers, and actually twice as great as among clergymen. These facts can bear only one interpretation. Medical men have many peculiar privileges; they are the recipients of great honour and of still greater confidence, and they hold in their hands many of the cords by which our social life is bound; but their life-work is often arduous, their life-course often short, and many fall from the ranks when the trumpet is only sounding for the battle and ere the conflict is well begun. It is comforting to reflect that many fall not the less truly martyrs in the cause of humanity, although their deeds are unsung and their heroism enshrined in the breast of perhaps one individual or in the affections of only a single household. The physician who sucks a tracheal tube to give an easy breath to the miserable victim of diphtheria, with the knowledge that the act too probably seals his own doom, is but the most distinguished illustration of a heroism which is part of the inheritance of the medical profession, and which is in daily, and often silent and unobtrusive, exercise in every part of the civilised world. Medical men "count not their life dear unto them," so that human suffering be mitigated and the dictates of honour and duty obeyed. This is their solemn obligation; it is also their privilege, for self-sacrifice is the law of the

Digitized by Google

moral universe, and its exercise is the surest path to personal happiness.

Let the student, then, on the threshold of his career realise that he is becoming the heir of noble traditions and the guardian of some of the most sacred rights of humanity Let him reflect that he is taking the first steps on a path which may become as the shining light. Let him clearly understand that on his zeal and diligence in the pursuit of knowledge turn not only his own honour and interest, but in all probability the lives and happiness of many of his fellow-men. The profession of medicine, embraced in this spirit and pursued with such sentiments, will be fruitful in usefulness and honour, and its professors at the conclusion of their labours will most assuredly be ranked among the number of the "righteous" who "shall be held in everlasting remembrance."

THE PRACTICAL ELEMENT IN MEDICAL EDUCATION.

ONE noticeable fact in the history of the year that may prove of interest to students of medicine is the appointment of a committee of the Medical Council, on the motion of Dr. GLOVER, to consider the best means of increasing the practical element in medical education. This element is, undoubtedly, a most important one in medical education. It is admitted on all hands that medical education is better now than it has ever been. The public demand is higher, the efficiency of schools is greater, and their rivalry is keener. The basis of education has been raised, and the whole superstructure with it, including all its special and professional branches. All the strictly scientific parts of medical education are now taught in many schools as they have never been taught before. In some schools a large proportion of the teachers practically devote their lifetime to their work. But in spite of all this—or, perhaps, partly because of it—it has been complained that there has been a falling off in the practical parts of medical education, and that the newly-fledged diplomate, or even graduate—though more transcendentally learned in minute anatomy, chemistry, physiology, and pathology than his predecessors, —is less apt at recognising and treating common diseases, upon which so much of his comfort and reputation in after life depend. Some physicians and teachers of great authority admit and approve this. They say that it is inevitable, and that a student cannot become a practitioner till he has practised. This is of course a truism, but it is not a sufficient answer to the complaint. As medical science has improved, so has medical art. It is more neat, more direct, more precise, altogether more apt than it used to be; and medical students should be better trained in this latter, as they are in the former respect. The power of early recognising scabies or scarlet fever, or a wrong presentation in midwifery, or a fracture in surgery, or a dangerous infantile diarrhœa, can be taught as well before the charmed diploma is given as after. So can the professional conduct proper to such discoveries. It is certainly possible to go through all the long and exacting existing curriculum of the Schools and learn nothing of these things. Some of the Schools have not the means of teaching them. With large museums and learned professors, they have not cases of disease and of midwifery such as constitute the bulk of medical practice.

It remains to be seen whether the Medical Council of Education can suggest or apply a remedy for this defect. The committee appointed has already presented a temporary report recommending a limited pupilage, the alliance with every hospital of dispensaries and midwifery departments, the requirement of a larger midwifery experience in students, and more attention on the part of the examining authorities in the final examinations to common diseases. But this report, by a somewhat circumlocutory process, has been referred to another committee, and the result is still uncertain.

Meantime we advise students, for their own sake, to cultivate the practical element in their own education; to learn for themselves early the interest of common cases, common remedies, and common causes of disease; to aim at readiness in detecting what is wrong, and in seeing the nature of the correctives that can be applied. Our recommendation is not in favour of dogmatism and quackery and a specific for every symptom, but in favour of the cultivation of a medical aptitude for detecting and removing the run of diseases for which people consult medical practitioners. No worthy student should wait for the action of medical authorities in demanding proof that he knows the profession on which his living and the life of his patients are to depend.

STUDENTS PAST AND PRESENT.

THE student of medicine has been, and still is perhaps, regarded by some as a person in whom the faults of humanity meet and multiply with peculiar facility. In addition to our common inheritance of moral frailty, his age and associations appear in the eyes of such to have impressed him with a large additional proneness to error which is all his own. They would dread his presence under the same roof, would treat him with particular caution as an acquaintance, and would be prepared to find him the active source of almost any mischief or misdeed. For them perhaps it is not unnatural to view him in this light. Some natures readily exaggerate every circumstance, good and evil alike. A greater number are too ready to magnify evil while they persistently minimise good, and this not so much by intention as by a physical law which has allotted too grave a shade for their mental atmosphere. The alarmists, to whom the fair fame of our profession while yet in its budding spring presents a picture so unpromising, belong to this latter class. They are too apt to view with disfavour even the natural and blameless exuberance of youthful energy. They forget that idleness and folly are not the only companions of young manhood, and that though these qualities may distinguish a minority of youths engaged in every calling, there is, happily for mankind, in medicine as in other spheres of labour, a majority which is endowed with some sense of responsibility and a resolution to do well. They forget, moreover, that a large part of the praise or blame for what a young man is must be borne by the age he lives in, and that as times and customs alter so does he. Whether the change be for the better or for the worse, this will appear no less in his character and conduct than in the lives of other men. Be his individuality what it may, he must in some degree be moulded by his time.

The fifty years of our QUEEN'S reign have been fruitful in

Digitized by Google

advantage to all callings and all conditions of men. They have witnessed the action of forces whose operation upon the mind and work of the medical profession have been of most happy kind—forces which have not failed to affect favourably the quality of our professional recruits. More has doubtless to be done, and it would be idle to argue that further advances do not lie before them and us. We are well aware that the medical student is no more perfect than other young men. This much, however, we may truly say of him, that he represents in some respects a marked improvement on the type of his predecessor of half a century ago. Now, we are not about to drag up old memories for the purpose of abusing them. The widely admitted skill and character of many older practitioners who still survive amongst us are not the outcome of a wild and idle youth. Good work and an honest conscience have been held in honour by many in schools of medicine since time was young. Nevertheless, there is, we assert, a difference between the student past and present, and this difference is on the whole in favour of the latter. The object of study is now more clearly kept in view than it was then; study itself is more in vogue; recreation, still in justly high esteem—nay, in freer exercise,—bears rather more the impress of manhood, less of boyhood than before; and life throughout has more the stamp of reality. Racket and dissipation certainly are not, and have not been, in recent times at least, the rule in medical student life; but it is equally true that they were once less exceptional than they are now. What cause has wrought this favourable change? It is not that sombre gravity has overweighted the buoyancy of youth, but that young men and all men find it profitable alike in personal satisfaction and in material advantage to be sincere in all things, active in timely amusement, and vigorous in timely work. Naturally and truly we may assign much of this improvement to the tendencies of the period in which we live. Overwork there is in plenty, and we do not praise it for that, but regulated effort there is also within even this excess, sense of duty, belief and hope in it, and in life as duty as much as in any former era—nay more. In this era, for which, amid all falsity, real or apparent, we claim the merit of comparative sincerity, we can see in actual life a frequent answer other than the cynic's to the cynic's question—Is life worth living? In the history of recent invention and discovery, in the great advances made by public opinion in matters of moral, intellectual, social, and physical well-being, there is not wanting something which replies for men in common: that life, if it be purposely lived—not dreamt or idled through,—is in their view worth living. This character of the age, this hopeful earnestness, has impressed itself in no undecided manner upon the mind and conduct of medical students.

Another factor which has assisted and still powerfully assists this class is the actual development which has taken place in our knowledge of medicine itself, with the practical results involved in that extension. In order to gauge the real meaning of this advance, it is not necessary to enumerate here the many successful researches which have added skill once believed impossible to the healing art. To every person possessed of ordinary intelligence and information it will be an easy matter to form a fair idea of that volume of scientific truth which, within a generation or two, has been collected into a common fund of intellectual capital for the use of all practitioners. Then, again, out of that increase of knowledge, how many mechanical facilities have arisen like a second growth to confer upon us advantages of the greatest value in diagnosis and treatment. More is almost daily known and done in medicine and surgery, and, as a natural consequence, the interest which belongs to the work increases in proportion. Not only does it command a wider and a deeper appreciation than at any former period at the hands of the general public, but it has proved repeatedly and fully its power of drawing out the enthusiasm and the energy of those who enter its ranks. Nor does this devotion imply merely a passing and ineffective exuberance of feeling. The sense of personal responsibility supplies an ever-present check upon any such excess; and while we naturally expect to find this the ruling principle in the mind of the practioner, we cannot but notice that it guides in an important degree the course of student life also. It is therefore not remarkable that, after passing in review these various considerations, we find in them so many reasons for the greater steadiness of endeavour which distinguishes the medical student of to-day from some of those who went before him. We cannot but think, too, that in fixing the limit of age at which a diploma can be obtained at a later period than formerly, the heads of the faculty have rendered useful service to students as well as to the non-medical part of the population. They have provided, as far as they can, that manhood, if not already reached, shall be near enough to guarantee a due regard for the exercise of energies which are not conducive merely to amusement. They have thus allowed the student time to form a fair estimate of what is implied in professional duty, and have enabled him to bring to bear on extended studies a more mature mind than was at one time thought to be necessary. It cannot be said, however, that this or any other existing arrangement has even come near to settling the question between work and play. That question is one affecting not youth alone, but every age, class, and occupation. However well we may try to advise with regard to it, its decision remains a matter of individual judgment, and compromise is the basis of such decision in every case. Recreation is as indispensable to a healthy life as work is to success in any undertaking. Even in its physical form it refreshes mind as well as body, and if rightly used will aid the student in his more laborious mental efforts without inflicting upon him any real disadvantage, for time thus occupied is repaid in working power. So it is with occupations of a recreative kind that are not physical. Change of mental as well as of muscular action is rest-giving and helpful. Who does not know the power of a fresh interest introduced amid fatigue and worry? How it changes nature in a man and sets the world about him and his part in its affairs in a totally different and more hopeful light from that of his former blurred and dim perceptions. It is no new saying that change is recreation, and it is true wisdom in students and in all men to see that in their most strenuous undertakings mind and body are not deprived of those refreshing interruptions of effort which are due to them. At the same time, we may be allowed to remind our readers that the real business of student life, the course of study, must always occupy the chief share of their attention. If they would assure a successful future, they must assign to

Digitized by Google

amusement, however salutary, a distinctly secondary position. This, it seems to us, is for medical students no hardship. Their mental occupation for the time being abounds in interest, and, inasmuch as it is largely practical, implies a fair degree of wholesome exercise. Their lot, therefore, even in its more laborious phase, is by no means unattractive, and may well absorb their best energies. Another subject directly connected with the employment of leisure is the choice of friends. The importance of making a right selection it is hardly possible to over-estimate. Temptations cluster around the path of all young men; and certainly the journey which the student of medicine has to travel is not beyond their influence. In view of this fact, it is not difficult to understand how the quality of a friendship has often a determining force towards good or evil, and we would strongly advise every student who does not intend his college life to be a failure not only to work regularly himself, but to choose his associates from the number of those who are good workers. In the sowing time of manhood some have thought it well to sow wild oats among their wheat. They have thought that the bitterness of the after-taste was compensated by the novelty of that light diversion while it lasted. But time is the truest teacher in all such matters, and the verdict of time is against that folly which winks at evil till it seems to be good, and kicks at restraints which impose no stricter bondage than that which the teaching of experience must otherwise establish. Strong fibre of mind or body is not bred of disease, and we repeat that what is most honourable and most useful in our professional character and practice is not, and never can be, the outcome of a profligate or idle studentship.

THE CHOICE OF A TEXT-BOOK.

THE question which the student is always asking, and naturally, is what book will best serve his purpose in preparing for certain examinations. The answer to this question is one which becomes every year more difficult The number of medical text-books of a high class is now very great; therefore to select a few from amongst them may seem invidious. At the same time a list, which by no means pretends to be exhaustive, can be drawn up that may prove of value as a guide to the student in his choice As representing all the various examining bodies, we may take for this purpose the Examining Board for England (Royal College of Physicians and Royal College of Surgeons) and the University of London.

THE EXAMINING BOARD FOR ENGLAND.

For the *First* Examination of this Board the student will be required to have gained a fair knowledge of Elementary Anatomy and Physiology, of Chemistry, Materia Medica, and Pharmacy; and if he be diligent he should be able to pass both parts of the examination by the close of his first year. In *Anatomy*, he may have recourse to GRAY'S Text-book, and to the works on *Osteology* by WARD, HOLDEN, and NORTON. In *Physiology*, the Elementary Text-book of HUXLEY might well be mastered first. In *Chemistry*, HOSCOE'S Elementary book and ATTFIELD'S work. In *Chemical Physics*, FOWNES' Inorganic Chemistry edited by WATTS, or BALFOUR STEWART'S Elementary Physics. In *Materia Medica*, the works of MITCHELL BRUCE, WHITLA, ROBERTS, GARROD, and BRUNTON'S or OWEN'S Elements.

For the *Second* Examination (corresponding to the Primary Membership at the College of Surgeons), the subject of *Anatomy* may be well studied in GRAY'S Anatomy, ELLIS'S Demonstrations, or HEATH'S Practical Anatomy. The anatomical plates of ELLIS and those of GODLEE are very useful in supplementing practical work, or the handier volume of MASSE. In *Physiology*, the books most to be recommended are KIRKE'S Handbook, G. YEO'S Text-book, and H. POWER'S Elements; and *Histology*, apart from the sections devoted to it in the works of GRAY and KIRKES, may be read in KLEIN'S Elements.

For the *Third* or Final Examination, in the subjects of *Surgery* and *Surgical Anatomy*, there are the Text-books of BRYANT, HOLMES, GANT, and ERICHSEN'S work, ably edited by MARCUS BECK, the System of Surgery edited by TREVES, the Practical Handbooks of BERKELEY HILL, CHRISTOPHER HEATH, PEARCE GOULD, and TREVES'S Applied Surgical Anatomy. For *Surgical Pathology* PEPPER or BILLROTH may be recommended. In *Diseases of the Eye*, LAWSON or NETTLESHIP. In *Medicine*, the Text-books of ROBERTS and BRISTOWE, preceded by the smaller works of CARTER or CHARTERIS. *Clinical Medicine*: FENWICK, FINLAYSON, or GRAHAM BROWN. *Pathology*: GREEN, COATS, and ZIEGLER (MACALISTER'S translation), and WOODHEAD'S or STEVEN'S practical work. *Therapeutics*: BARTHOLOW, RINGER, NAPHEYS, and FARQUHARSON. *Medical Jurisprudence*: the Text-books of GUY and TAYLOR. *Public Health*: WILSON. *Midwifery*: PLAYFAIR or GALABIN.

COLLEGE OF SURGEONS (FELLOWSHIP).

In addition to the anatomical and physiological works above mentioned, there may be read for the Primary F.R.C.S. (especially its histological and embryological sections)—QUAIN'S Anatomy, FORSTER'S Text-book of Physiology, LANDOIS' work edited by STIRLING, and GEGENBAUR'S Comparative Anatomy. Professor FLOWER'S Osteology of the Mammalia might also be read. For the Pass Examination, ERICHSEN'S work may be supplemented by chapters in the System of Surgery edited by HOLMES and HULKE. In *Operative and Practical Surgery*, there are works by STIMSON, FERGUSSON, and S. SMITH and HEATH'S ATLAS. PAGET'S or BILLROTH'S Surgical Pathology and ZIEGLER'S Pathology may be profitably read in connexion with works mentioned under the Conjoint Examination.

UNIVERSITY OF LONDON EXAMINATIONS.

For the Intermediate M.B. Examination of the University of London, the subject of *Organic Chemistry* may be studied in the Text-books of WILLIAMSON and of FOWNES. *Materia Medica*, besides the books above mentioned, is more fully treated in the works of BRUNTON, PHILLIPS, BARTHOLOW, and H. G. WOOD. *Physiology* as for the Primary F.R.C.S., with perhaps the addition of such books as that of POWER and HARRIS for practical work and of SCHAFER for practical histology. The anatomical text-books are those recommended above. For the M.B. Examination, the subject of *Medicine* may profitably be further studied in NIEMEYER'S Text-book, in the exhaustive and scientific treatise of the late Dr. HILTON FAGGE, in that of AUSTIN FLINT, in the admirable work of STRUMPELL, lately translated, in REYNOLDS'S System of Medicine, and in TROUSSEAU'S Lectures. The large System of Medicine by American authors contains articles which

Digitized by Google

may often be usefully consulted by those who are desirous of obtaining full and accurate information. Special monographs (see M.D. Exam.) may also be consulted. *Pathology*, which should be worked at practically, may be studied in GREEN'S, COATS', or ZIEGLER'S Text-books, and also in the works of WILKS and MOXON, and in those of CORNIL and RANVIER; *Midwifery*, in the writings of PLAYFAIR, GALABIN, LEISHMAN, LUSK, and BARNES; *Gynæcology*, in those of GALABIN, LOMBE ATTHILL, EDIS, M. JONES, and BARNES; *Dermatology*, in the Text-books of TILBURY FOX, LIVEING, DUHRING, and M. MORRIS; *Medical Electricity*, in DE WATTEVILLE or POORE; *Medical Ophthalmoscopy*, in GOWERS' Handbook. For the M.D. Examination the candidate will do well to extend his reading to the better-known monographs, such as MURCHISON on Continued Fevers and on Diseases of the Liver; GOWERS, ROSS, CHARCOT, and WILKS on Diseases of the Nervous System; BALFOUR, BYROM BRAMWELL, and WALSHE on Diseases of the Heart; POWELL and WALSHE on Diseases of the Lungs; RALFE, W. ROBERTS, and DICKINSON on Diseases of the Kidney; E. SMITH, GOODHART, and A. MONEY on Diseases of Children.

In the foregoing lists we have mostly indicated more than one work upon a subject; for it is, of course, impossible to make a single selection from among so large a number of excellent works. A certain amount of choice must be left to the student himself, who will do well to be guided in this respect by the opinion of his teacher in the particular subject. Since it is impossible as well as undesirable for him to be too discursive in his reading during his student days, he may well resolve to devote such leisure as may happen to him in the future to making the acquaintance of works which will afford not only instruction but pleasure in the perusal.

CONDITIONS UNDER WHICH MEDICAL MEN WITH BRITISH QUALIFICATIONS ARE PERMITTED TO PRACTISE IN FOREIGN COUNTRIES.

MEDICAL men are so frequently anxious to settle abroad that a little general information concerning the conditions under which those who possess British qualifications can obtain permission to establish themselves in practice in various countries will probably be useful. As new laws are made these conditions are liable to change, and at the present time the regulations for the permission of foreigners to practise are in a transition state in several of the more important countries. There is probably no country in Europe where more liberty is enjoyed by foreign practitioners than in England; while other countries are continually hedging themselves round, so that it is yearly becoming more and more difficult for a British practitioner to establish himself abroad unless he is prepared to undergo a tolerably complete examination in all the subjects of medical study in the language of the country in which he elects to live. A British diploma ought to hold good for all British possessions. In some colonies, however, local fees have to be paid, and in Malta we believe an examination is required, though by what right it is difficult to conjecture.

In France there are two grades of practitioners—Officers de Santé and Doctors of Medicine, the examinations for the former diploma being fewer and more simple than for the latter. It has been usual for British medical men to content themselves with the lower diploma, which, it should be remarked, gives only a right to practise in some one department of France. Now, however, a cry has been raised that foreigners ought to be obliged to undergo the whole of the five examinations for the Doctorate—if not, indeed, to pursue their studies over again in a French medical school. Discretion is given to the Minister of Public Instruction to decide whether a foreign medical man may be admitted to the examinations for the Officership or the Doctorate, as well as the amount of exemption that shall be accorded to him. This decision is based upon the value of his own diplomas.

In Germany the ordinary State examination must be passed, and as a condition of admission to it the maturity or matriculation examination must either be passed or exemption obtained from it on the strength of some degree or other Arts examination previously passed at home. Some account of the German and other continental examinations was given in the Students' Number of THE LANCET for 1886.

In Austria, save, we believe, under very exceptional circumstances, when leave to practise may be obtained from the Government, the M.D. of an Austrian University is essential. We are not able to say whether the usual conditions as to residence may, as a rule, be dispensed with.

In Russia the State examination must, as a rule, be passed—in Russian at most of the Universities, in German at Dorpat, or in Swedish at Helsingfors. The Helsingfors diploma, however, only holds good for Finland. Where a foreign M.D. of high value is held, the Minister may permit the examination to be confined to what is called in Cambridge "keeping an act"—i.e., reading and defending a thesis. Even this is a much more serious affair than it is generally looked upon with us.

In Switzerland, the State examination is compulsory, and it is said to be by no means a matter of form by Englishmen who have passed or attempted it. It may be passed in French or German.

In Holland the State examination, which, we believe, corresponds somewhat with the German one, must be passed.

In Denmark the degree of Candidate in Medicine must be taken at Copenhagen. Foreign practitioners are admitted without residence.

In Sweden and Norway a State examination must be passed. These Scandinavian examinations have the reputation of being very severe.

In Portugal, including of course Madeira, the regular State examination must be passed in the Portuguese language.

In Italy permission may be obtained to practise amongst foreigners, but in order to practise amongst Italians the M.D. degree must be taken at one of the numerous Italian Universities.

With regard to Spain, application must be made through the diplomatic agent to the Government, the diplomas, duly certified, being forwarded. The application is usually granted, but applicants must be prepared for protracted delay; thus we have information that one gentleman who applied more than a year ago is still in a state of suspense.

Digitized by Google

In Belgium either a degree must be obtained from Ghent or Liège (those of Brussels and Louvain not being recognised), or an examination of a more or less formal character must be passed, after which a "permit" is given by the Minister. Changes in the direction of increased stringency may here be expected shortly.

In Servia an examination must be passed in Belgrade, except by graduates of Paris or Vienna.

In Roumania a *vivâ voce* examination is necessary.

In Turkey a short examination is obligatory, which is held at the Military Medical School; but although the regulations appear simple enough, we are informed that there are various difficulties to be overcome before obtaining the necessary licence.

In Greece an examination is necessary, which is held at Athens. It may be conducted in almost any language.

In Egypt and Morocco permission to practise may be obtained by the presentation of British diplomas.

In the United States the laws vary with the different States. In most of them British diplomas are recognised. In New York, however, a degree must be obtained from some local college.

Nearly all the South American States require examinations to be passed. Some of them are really difficult, and others are said to vary in stringency according to circumstances, the examiners, who are frequently Englishmen or Germans, not being particularly anxious to increase the already existing competition for practice amongst the more wealthy inhabitants.

THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

DURING the past year no change has been made in the qualifications required of candidates for commissions in the Medical Services, nor in the regulations affecting the pay and retirement of the officers. The Navy, the Army, and the Indian Service, differing from each other in some respects, but all possessing considerable advantages, seem to us to offer eligible openings for young medical men. Candidates for the Navy do not enjoy the benefit of the valuable course of instruction given to the other two branches at Netley, but they come upon full pay from the date of passing the competitive examination. Naval medical officers have great opportunities of seeing foreign countries and of studying natural history in its various branches, if so disposed, and have abundance of time for study. But, on the other hand, their opportunities of following out the practical work of their profession are limited, and they are liable to be placed on half-pay for indefinite periods when their ship is paid off. The latter drawback has been much reduced in recent years by the judicious action of the Director-General in employing them as much as possible in the hospitals on shore, but the possibility of this compulsory half-pay must not be overlooked. Candidates for the Army have the benefit of a most valuable course of instruction at Netley on special subjects, which cannot fail to prove useful to them in their future career and enable them, from the very commencement of their service, to carry out their duties with satisfaction to themselves and benefit to the soldier. Like the naval officers, though in a different manner, they have the opportunity of seeing foreign lands, but are not liable to be placed on half-pay on their return to England. They have also the right to retire from the service after completing a period of ten years, with a gratuity of £1250; after fifteen years, of £1800; and after eighteen years, of £2500. They labour under the disadvantage, however, of not being allowed to count the period of service at Netley towards retirement, their commissions being dated from the termination instead of the commencement of the course. They are by this also placed in the position of being always junior to the medical officers of the Navy and the Indian Service who have passed at the same competitive examination. Admission to the Indian Medical Service is governed by the same conditions as those which obtain with regard to the Army, and, as surgeons on probation, entrants have the advantage of the course of instruction at Netley. Their commissions as surgeons are antedated to the period of their joining at Netley, and the four months passed there are reckoned as service for pension; but their pay between the date of passing the final examination at Netley and arrival in India is only ten shillings per diem. The Indian medical officers labour under the disadvantage that all their service must be tropical, and they do not seem to have a right, as in the Army, to retire upon a gratuity after stated periods; but they become entitled to retired pay after seventeen instead of twenty years. The officers of the administrative grades are granted also a higher rate of retirement than those in the Army. We have endeavoured to point out the leading differences in the three branches with a view to enable students to weigh well their relative advantages and disadvantages; but we think all three offer considerable inducements in the way of pay and retirement to young men who may desire to enter at once upon a career in which, from its commencement, they can live on their pay, and have also the right either to retire when they think fit, or to continue to serve with the certainty of a fair pension for life.

METHODS OF OBTAINING A PRACTICE.

DURING his hospital days a student's whole energies are very properly thrown into the labour of preparing for his examinations and fulfilling the duties attached to the appointments he has been fortunate enough to obtain. It is, however, after his diplomas have been gained that the real battle of life begins. As long as he was at the hospital all was tolerably straightforward, and any lecturer or senior student could give him advice as to the course that should be pursued; but when the student has become a practitioner, or rather a medical man, no one can advise him how to obtain patients, and guarantee that the advice, however faithfully followed, will lead to success. A good student who has taken honours in his examinations and held important hospital appointments does not by any means always command the success in after life which he feels is his due. Indeed, he not unfrequently finds that some fellow-student who has taken no honours, and whose ability he perhaps looks upon with contempt, succeeds in obtaining a much better practice than himself. Not all the public care whether their medical man is an M.D. Lond. or an L.S.A., but they care very much for agreeable manners and tact. Leaving aside for the present the comparatively small number of young practitioners who wish to become consultants, as well as those who enter the public services, and addressing ourselves to those who look

Digitized by Google

forward to general practice as the means of earning their daily bread, a few hints as to the methods that exist of obtaining or attempting to obtain a practice may be of some utility.

It is often thought that an active young man has only to offer to do the bulk of the more arduous work of a practice for an elderly practitioner in order to be taken with open arms as a partner. There could not be a greater mistake. An elderly practitioner who wishes to part with a share of his practice—i.e., of course of his income—can always find a junior partner who will gladly pay him a substantial sum for it, and few men will give away that which has a marketable value. The purchase of a partnership, therefore, is one method of obtaining a practice, and a very suitable method for a young man who has had no experience as pupil or assistant in a general practice. The price that has to be paid varies generally from one and a half to two years' purchase of the share purchased. Thus, suppose the average income for the three preceding years is shown by the books to be £1200, a third share will have a value of from £600 to £800. If the practice does not decrease, he will immediately commence to *earn* £400 a year, but he will be some time before he *receives* anything to speak of, as accounts are not generally sent out more often than half-yearly, and may then remain unpaid for a considerable period. The junior partner will do well to reckon that during his first year he will not receive more than the half of what he has earned, or £200. During this time, however, he will have, in addition to the necessary outlay on furnishing, to pay rent, to keep himself and his family, if he be married, in suitable style, and to bear his share of the outgoings of the practice for drugs, bottles, and stationery, and if the vehicular expenses are borne by the firm, for the horse and man in addition. All this shows that even such a small partnership as this cannot be entered into without some capital over and above the amount paid as premium. Speaking generally, it may be said that a man should not expend more than 60 or 70 per cent. of his available capital in the purchase of his share. Such a share as we have supposed should not therefore be thought of by a man with less capital than £900 or £1000. Partnerships are becoming more and more rare, and there are, of course, objections to them. For instance, a partnership may be a great tie, for it may not be easy to liberate oneself from it, however much the locality may disagree with oneself or with one's family. Many ways of improving the practice or the manner in which it is conducted may occur to the junior partner, but he cannot well carry them out against the wishes of his senior. For these and other reasons it is more usual to buy an entire practice than a mere share in one. Would-be purchasers of practices should, however, be warned that all that can be bought is an introduction to patients and the goodwill of the retiring practitioner. A man may be ever so well qualified, and even experienced, and yet he may find that after his predecessor has left, a large proportion of the patients may fall away; that is to say, they may prefer the attendance of some other practitioner whom perhaps they may have known, socially or by repute, for many years. Small practices are much more easily transferred than others. Generally speaking, where the patients are of a high class and there is much opposition, transfer is difficult; whereas in a country village where there is no opponent for several miles, the transfer of a large proportion of the patients may be confidently looked for—i.e., if the parochial appointments can be secured; if not, the practice is probably not worth buying at any price. The premium paid for an entire practice is under ordinary circumstances about a year's purchase of the gross receipts, with a preliminary partnership of three, six, or twelve months on equal terms. What is called a death vacancy can frequently be obtained for half a year's purchase. It is well for the incomer to remember that he will have to keep up much the same establishment as his predecessor upon what is likely to prove only a half or two-thirds of his income, and that some time—in country places a year or eighteen months—will probably elapse before much begins to come in.

It is impossible within the limits of an article to go into a detailed account of the matters on which an intending purchaser should inform himself—such as the appointments, the number of midwifery cases (and whether these are increasing or diminishing), the conditions of opposition, increase or decrease of population, conditions of tenure of the house, the general character of the vendor and the length of time he has held the practice, the possibility of obtaining accommodation during the introduction, whether the connexion is sectarian, &c. He must beware of accepting too literally the statements and views of a would-be vendor, who sometimes romances cheerily and in much too sanguine a strain on what may be accomplished by a more active or a more highly qualified successor. Vacant practices are to be heard of through private friends or the members of the hospital staff, by taking locum tenencies, and through advertisements, wholesale druggists, or medical agents, but in all cases *caveat emptor*. A respectable independent medical agent will for a very few guineas make inquiries, examine the books, and give advice about the value of a practice both generally and to the individual client, and about the terms of the agreement. It is part of his profession to do this, and many a medical man would have saved himself from severe disappointment by taking timely professional advice. Of course the family solicitor should also be consulted, but he has not usually the special knowledge of an experienced medical agent regarding the details of medical practice.

The question is often asked by recently qualified men on the look out for practices, What income may I fairly hope to obtain by the investment of my capital? Of course, a great deal depends on the individual and much on the locality of the practice. Speaking in very general terms, it may be said that if 60 per cent. is sunk as premium, the remaining 40 per cent. being employed in furnishing and in maintaining oneself until the practice yields its full fruit, a gross yearly income of 40 or 50 per cent., or a net income of 30 or 40 per cent of the total original capital may fairly be looked for, whether the premium is invested in a partnership or in an entire practice; that is to say, a man with £1000 ought to make a net income of £300 or £400. Of course, many men succeed in doing much better than this, either by buying a practice on peculiarly favourable terms, or by equalling or exceeding the outgoer's income from the very first. Thus, we know of a case where a man "picked up" a practice just as it was about to be abandoned for £60, with a fortnight's

Digitized by Google

introduction, and succeeded in making £300 a year at once; he had, however, some private means. It should be remarked that a very small practice is frequently not worth buying at any price, the necessary expenses reducing its net value far below that of an assistancy. Indeed, where the available capital is, say, under £500, it is worth consideration whether it is not better to invest it at compound interest in some public security, and to take an assistancy till a favourable opportunity (which is nearly sure to come sooner or later) can be seized.

Medical men who have no capital or connexion are frequently attracted by assistantships, with a view to partnership. In nine cases out of ten the "view" turns out to be of a most telescopic character, unless there is a written and stamped agreement, and a readiness of capital when the share is actually transferred. Practices may sometimes be created by "setting up" in a new neighbourhood which is rapidly growing; or in a place where one already has some connexion either through relatives or friends, or through having been house-surgeon at the local hospital. Again, a practice may sometimes be made by obtaining some parochial or other appointment which is publicly advertised, and which of itself affords an introduction. Such appointments, however, are not very easy to obtain, and much time and money are sometimes wasted in applying for posts and interviewing guardians when the appointment is already as good as made, and the advertisement is a mere matter of form. It is rare that a practice can be made without the expenditure of some capital, for even if success ultimately attends the venture, the practitioner has to "sit behind his brass plate" to pay his rent and to maintain himself for some months, or even years, before sufficient practice is obtained to support him, so that, as Dr. THURSTAN recently remarked in our correspondence columns, it is financially much the same thing whether a practice is made or purchased. Complete failure, too, is probably more common in cases where men have established themselves in a fashionable locality in an expensive house, without adequate means, than in those where a practice of some kind has been bought. Here the purchaser seldom fails to secure some remnants of his predecessor's practice, which, though perhaps very much less than he had hoped for, are yet sufficient to enable him to exist; whereas, when there has been no introduction, some years may elapse before £100 is received.

A WORD TO STUDENTS OF PSYCHOLOGY.

IT is not to be expected that a knowledge of insanity, any more than of other branches of medicine, can be obtained by the light of nature. The public are occasionally under the delusion that anyone is able to recognise a lunatic at first sight. In many instances, no doubt, this supposition is correct, but in a very considerable number of cases the diagnosis is one of extreme difficulty. Practitioners, therefore, who have any dealings with lunatics should be able to prove that they are competent to undertake their management. During the last twelve months a step in the right direction has been taken by the Medico-Psychological Association, and we are glad to find that the recommendation contained in our Students' Number of last year, that those who intend to treat the insane should obtain the diploma offered by this body, has not been neglected. The fact that not less than twenty-four registered practitioners have availed themselves of the opportunities of being examined by distinguished psychologists, and of displaying their competency to treat mental disorders, is sufficient proof that the Association has supplied a want, felt not only by the profession, but also, we venture to think, by the public. We shall watch the progress of this movement with much interest, and we trust that all our recognised examining bodies may be induced to follow this good example, and to insist upon a knowledge not only of the book work, but also of the practical knowledge of mental disease, being exhibited by those who receive their qualifications. Latterly several cases have come under our notice in which great difficulty has been experienced in getting medical men to sign certificates for admissions to asylums. This under present circumstances is hardly to be wondered at. Should the proposed new Lunacy Bill ever be passed, we sincerely hope that the most stringent measures will be taken to protect those who are really acting conscientiously from the mental anxiety, loss of time, and loss of money to which some of our profession have recently been subjected.

SESSION 1887-88.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Registration of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in Medicine:—

Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council,[1] and has produced evidence that he has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. The registration of medical students shall be placed under the charge of the branch registrars. Each of the branch registrars shall keep a register of medical students according to a prescribed form, and shall enter therein the name, the preliminary examination and date thereof, the date of registration, and the place and date of commencement of medical study, as certified by a master or a teacher, or an official in a medical school or hospital. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and *evidence that he has commenced medical study*. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. The several Branch Councils—and in England the Executive Committee, if its meeting be more convenient, and the case be urgent—have power to admit special exceptions to the foregoing regulations as to registration.

[1] Exception may be made in the case of a student from any Indian, Colonial, or Foreign University or College, who shall have passed the matriculation or other equivalent examination of his University or College, provided such examination fairly represents a standard of general education equivalent to that required in this country.

Digitized by Google

for reasons which shall appear to them satisfactory. A copy of the Register of Medical Students, prepared by each of the branch registrars, shall be transmitted on or before December 31st, in each year, to the registrar of the General Council, who shall, as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an alphabetical list of all students registered in the preceding year, and supply copies of such authorised list to each of the bodies enumerated in Schedule A to the Medical Act (1858), and through the branch registrars to the several medical schools and hospitals. The several qualifying bodies are recommended not to admit to the final examination for a qualification under the Medical Acts any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months previously. In the case of candidates from other than schools of the United Kingdom, the Branch Councils—and in England the Executive Committee, if its meeting be more convenient and the case be urgent—have power to admit exceptions to this recommendation. The regulations for preliminary general education are as follows:—

No person shall be allowed to be registered as a medical student unless he shall have previously passed (at one or more examinations) a preliminary examination in the subjects of general education as specified in the following list:—1. English Language, including Grammar and composition. 2. Latin, including Grammar, Translation from specified authors, and Translation of easy passages not taken from such authors. 3. Elements of Mathematics, comprising (*a*) Arithmetic, including Vulgar and Decimal Fractions; (*b*) Algebra, including Simple Equations; (*c*) Geometry, including the first book of Euclid, with easy questions on the subject matter of the same. 4. Elementary Mechanics of Solids and Fluids, comprising the Elements of Statics, Dynamics, and Hydrostatics. 5. One of the following optional subjects:—(*a*) Greek, (*b*) French, (*c*) German, (*d*) Italian, (*e*) any other Modern Language, (*f*) Logic, (*g*) Botany, (*h*) Zoology, (*i*) Elementary Chemistry.[2]

W. J. C. Miller, B.A., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W.—James Robertson, Registrar of the Branch Council for Scotland, 4, Lindsay-place, George IV. Bridge, Edinburgh.—R. L. Heard, M.D., Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

REGULATIONS
OF THE
MEDICAL EXAMINING BOARDS IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.

There are two degrees in Medicine, B.M. and D.M., and two degrees in Surgery, B.Ch., and M.Ch., and a diploma in Public Health. The B.M. and B.Ch. degrees are granted to those members of the University who have passed the Second Examination. Graduates in Arts (B.A. or M.A.) are alone eligible for these two degrees. After the degree of B.A. is obtained, the degrees of B.M. and B.Ch. may be obtained by passing the following examinations:—1. Preliminary. 2. Professional. (*a*) First Examination: Subjects—Organic Chemistry, unless the candidate has obtained a first or second class in Chemistry in the Natural Science School; Human Physiology, unless he has obtained a first or second class in Animal Physiology in the Natural Science School; Human Anatomy. (*b*) Second Examination: Subjects—Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene, and Materia Medica with Pharmacy.

The degree of D.M. is granted to Bachelors of Medicine of the University—(1) who took the degree of B.M. previously to the end of Trinity Term, 1886, provided they have spent three years in the practice of Medicine after taking that degree, and have composed a dissertation on some medical subject approved by the Regius Professor of Medicine, before whom it must be read in public; (2) who took the degree of B.M. subsequently to the end of Trinity Term, 1886, provided they have entered their thirty-ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of B.M. whose subject is dealt with. A book published within two years of the candidate's application for the degree may be substituted for a dissertation. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House-Surgeon in such a hospital for six months, and who have passed an examination in Surgery, Surgical Anatomy, and Surgical Operations.

The diploma in Public Health is granted only to Bachelors of Medicine of the University who have passed an examination in Hygiene, Sanitary Law, Sanitary Engineering, and Vital Statistics.

The First Examination for the degrees of B.M. and B.Ch. and the Examination in Materia Medica and Pharmacy may be passed as soon as the Preliminary Examination in Medicine has been completed. Organic Chemistry may be taken on a separate occasion, but before Human Physiology and Anatomy. The two last-named subjects must be taken together. For exemptions, see *ante*.

The Second Examination may be taken after the completion of the first. Materia Medica and Pharmacy, if not already passed, may be offered on a separate occasion, but before the remaining subjects, which must be taken together.

The Professional Examinations in Medicine are held once a year in Trinity Term, the second before the first.

Instruction in the subject-matter of Responsions, Moderations, and the various literary schools is given by the tutors and lecturers of the Colleges and Halls. In Natural Science, the professors of the University and their assistants deliver regular courses of lectures and conduct classes for practical instruction in the laboratories of the Museum and Botanic Garden in each term. In addition, several Colleges possess tutors in Science, and in two or three instances laboratories as well. In Medicine, instruction in Organic Chemistry is given once a year. Physiology, Physiological Chemistry, and Histology are taught by the Waynflete Professor of Physiology and his assistants; Human Anatomy by the University lecturer in that subject, under whose control is placed the department for dissection. Provision for the teaching of Materia Medica is being made. Instruction and demonstrations in Physical Diagnosis and Regional Anatomy are given in each term at the Radcliffe Infirmary. Clinical lectures in Medicine and Surgery are also delivered by the two Lichfield lecturers of the University, a physician and a surgeon of the infirmary respectively; but as full provision does not exist for the teaching of the subjects for the Second Professional Examination (except Materia Medica), it is necessary for a student to obtain his knowledge elsewhere. The Radcliffe Library at the Museum contains a vast collection of scientific and medical literature, available for study and consultation by students.

Scholarships, &c.—Scholarships in some branch of Natural Science (Chemistry, Physics, Biology) of the average annual value of £80 per annum, tenable for four years and renewable under certain conditions for a fifth year, as well as Exhibitions of a less annual value, are awarded after competitive examination, every year by some, from time to time by other, Colleges. Notices of vacancy &c. are published in the *University Gazette*. In February there is competed for annually, by those who have obtained a first class in any school (Moderations or Final), or a Scholarship or Prize open to general competition in the University, one Radcliffe Travelling Fellowship. It is tenable for three years, and is of the annual value of £200. The examination is partly scientific, partly medical. The holder must travel abroad for the purpose of medical study, and take the degree of B.M. Oxon. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford or Cambridge of not more than ten years' standing for an original research in some Biological subject, including Physiology or Pathology.

More detailed information may be obtained from the University Calendar; the Examination Statutes, 1887, which contains the official schedules of the several subjects of examination in both Arts and Medicine; from the Student's Handbook to the University; from the Regius Professor of Medicine; from the Professors in the several departments; and from the Sub-Librarian in the Radcliffe Library at the Museum.

[2] The list of students in Universities with a prolonged curriculum, where matriculation in Mechanics required for their degree is taken at a [illegible] period of study than before commencing medical [illegible] can be effected only on having passed the [illegible] Mechanics, but their registration may be then antedated [illegible] when the Preliminary was passed.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep terms for three years by residence in the University. He must pass the Previous Examination in Classics and Mathematics, which may, and should if possible, be done immediately on coming into residence in October, or, which is best, obtain exemption through the Oxford and Cambridge Schools Examination Board or the Local Examinations, before commencing residence. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may proceed to take a degree in Arts, either continuing mathematical and classical study and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes. The Natural Sciences Tripos is the most appropriate, as the subjects are the same as those for the First and Second M.B. Examinations.

For the degree of *Bachelor of Medicine* five years of medical study are required, except in the case of medical students who have graduated with honours as Bachelors of Arts, four years only being then required, though it is rarely sufficient. This time may be spent in Cambridge or elsewhere. The first three or four years are usually spent in Cambridge, the student remaining in the University till he has passed (say) the examination for the Natural Sciences Tripos and the first and second examinations for M.B. Cambridge being now a complete School of Medicine, all the requisite lectures and hospital practice may be attended here, and many students remain to attend lectures and hospital practice until they have passed the first part of the third examination for M.B. The supply of subjects for Dissection and Practical Surgery is unusually abundant.

There are three examinations for M.B. The *first* in Chemistry and other branches of Physics, and in Elementary Biology. These may be taken together or separately. The *second* in Human Anatomy and Physiology, and in Pharmaceutical Chemistry. These may be taken together or separately. The *third* may be also taken in two parts—viz., (1) Principles of Surgery (with Operative and Clinical Surgery) and Midwifery and Diseases of Women, and (2) Pathology, Principles and Practice of Medicine, Elements of Hygiene, and Medical Jurisprudence. The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting-room, and in the laboratories.

Previously to the first examination, Lectures must have been attended on Chemistry (with manipulations). Previously to the second examination, the student must have attended Lectures on Human Anatomy, Pharmacy and Pharmaceutical Chemistry, and Physiology, have dissected for six months, and attended Hospital Practice six months. Previously to the first part of the third examination, he must have attended Lectures on Pathology, the Principles of Surgery and Midwifery, the Surgical Practice of a Hospital with Clinical Lectures for a year, ten cases of Midwifery, and produce a certificate of proficiency in Vaccination. Previously to the second part of the third examination, he must have attended Lectures on the Principles and Practice of Physic, the Physiological Action and Therapeutic Uses of Drugs, and Medical Jurisprudence; also the Medical and Surgical Practice of a Hospital with Clinical Lectures for three years, and have been Clinical Clerk for six months; and have acted as House-Surgeon or Dresser for six months, and have gone through a course of instruction in Practical Surgery.

The degree of *Doctor in Medicine* may be taken three years after that of M.B. An Act has to be kept, with *viva-voce* examination; and an extempore essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine.

As Operative and Clinical Surgery now form parts of the third M.B. examination candidates who have passed that examination are admitted to the degree of Bachelor of Surgery (B.C.), without separate examination.

For the degree of *Master in Surgery* (*M.C.*) the candidate must have passed all the examinations for B.C. two years. He is required to pass an examination in Surgical Anatomy and Surgical Operations, Pathology, and the Principles and Practice of Surgery.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, and Pharmacy may be obtained by sending a stamped directed envelope to the Assistant-Registrar, Cambridge. Full information is contained in the *Cambridge University Calendar*.

UNIVERSITY OF LONDON.

The *Matriculation Examinations* take place on the second Monday in January and the third Monday in June. Candidates must be above sixteen years of age. The fee for the examination is £2. Provincial examinations are appointed by the Senate from time to time at specified centres. Several scholarships, exhibitions, and prizes are associated with these examinations.

The *Preliminary Scientific (M.B.) Examination* takes place twice in each year, once for Pass and Honours, commencing on the third Monday in July, and once for Pass candidates only on the third Monday in January.[3] No candidate will be admitted to this examination until he shall have passed the Matriculation Examination, nor unless he have given notice of his intention to the registrar at least one calendar month before the commencement of the examination. Fee for this examination, £5.

Candidates are examined for a Pass or for Honours on Inorganic Chemistry and Experimental Physics; and for a Pass, on General Biology. Candidates for Honours, who have entered for the whole examination, may also be examined in Botany and Vegetable Physiology, and Zoology, unless they have previously obtained an exhibition in any one of the subjects of this examination at the Intermediate Examination in Science, in which case they shall not be admissible to the examination for Honours in that subject.

Bachelor of Medicine.—Every candidate for the degree of Bachelor of Medicine will be required—1. To have passed the Matriculation Examination in this University. 2. To have passed the Preliminary Scientific Examination. 3. To have been engaged in his professional studies during four years subsequently to passing the Preliminary Scientific Examination[4] at one or more of the medical institutions or schools recognised by this University, one year at least of the four to have been spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine.

Intermediate Examination.—The Intermediate Examination in Medicine takes place twice in each year, once for Pass and Honours, commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January, the January examination being held for the first time in 1888. No candidate shall be admitted to this examination unless he have passed the Preliminary Scientific Examination at least two years previously, and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having, subsequently to having passed the Matriculation Examination, been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the subjects in the following list: Descriptive and Surgical Anatomy, Histology and Physiology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine. 3. Of having, subsequently to having passed the Preliminary Scientific Examination, dissected during two winter sessions. 4. Of having, subsequently to having passed the Preliminary Scientific Examination, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry, in applying tests for discovering the adulteration of articles of the materia medica and the presence and nature of poisons, and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 5. Of having attended to Practical Pharmacy, and of having acquired a practical knowledge of the preparation of medicines. These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the registrar at least fourteen days before the commencement of the examination. Fee for this examination, £5.

Candidates will be examined in the following subjects: Anatomy, Physiology, Histology, Materia Medica and Pharmaceutical Chemistry, and Organic Chemistry.

[3] Candidates for the degree of M.B. are required by the Senate to pass the Preliminary Scientific Examination before commencing their regular medical studies, and are recommended to devote a preliminary year to preparation for it, according to the following programme:—Winter Session: Experimental Physics, Chemistry (especially Inorganic), Zoology. Summer Session: Practical Chemistry (Inorganic), Botany.

[4] Candidates who passed the Matriculation Examination in January, 1885, or previously, will be allowed to date the commencement of their professional studies, as heretofore, from that examination.

Digitized by Google

Every candidate for the July examination, on sending in his name for the examination, must state whether he intends to compete for honours in any subject or subjects; and, if he does so intend, must specify the subject or subjects. No candidate will be allowed to take both the Pass and the Honours Papers in the same subject; but every candidate must take the Pass Papers in those subjects in which he does not offer himself for Honours. A candidate who enters for, but fails to obtain, Honours in any subject, may be recommended by the examiners for a Pass in that subject if they are satisfied that he has shown such a competent knowledge thereof as is required by the regulations for the Pass Examination.

M.B. Examination.[5]—The M.B. Examination takes place once in each year, and commences on the last Monday in October. Each candidate, two academical years after passing the First Examination, must produce certificates to the following effect:—1. Of having passed the Intermediate Examination. 2. Of having, subsequently to having passed the Intermediate Examination, attended a course of lectures on each of two of the subjects enumerated in Section 2 of the regulations for that examination, and for which the candidate had not on that occasion presented certificates. 3. Of having conducted at least twenty labours. Certificates on this subject will be received from any legally qualified practitioner in medicine. 4. Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine. 6. Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the Intermediate Examination, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union, during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in Clauses 4 and 5. 7. Of having acquired proficiency in Vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The candidate must also produce a certificate of moral character from a teacher in the last school or institution at which he has studied, as far as the teacher's opportunity of knowledge has extended. The fee for this examination is £5.

Candidates will be examined in the following subjects: General Pathology, General Therapeutics and Hygiene, Surgery, Medicine, Obstetric Medicine, Forensic Medicine. The examinations will include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry.

Any candidate who has passed the M.B. Examination may be examined at the Honours Examination next following the M.B. Examination at which he has passed for Honours in (1) Medicine, (2) Obstetric Medicine, and (3) Forensic Medicine. The examinations commence in the week following that in which the Pass Examination terminated. Except in the case of Forensic Medicine, they are conducted by means of printed papers, but the examiners will not be precluded from putting *viva-voce* questions upon the written answers of the candidates.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year, and commences on the Tuesday following the first Monday in December. Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery, and of having operated on the dead subject. Fee for this examination, £5.

Any candidate who has passed the B.S. Examination may be examined at the Honours Examination next following the B.S. Examination at which he has passed for Honours in Surgery. The examination takes place on Tuesday in the week following the Pass Examination, and is conducted by means of printed papers.

Master in Surgery.—The examination for the degree of Master in Surgery takes place once in each year, and commences on the first Monday in December.

[5] Any candidate for the M.B. Examination who has passed the Intermediate Examination under the former regulations will be required to have passed the examination in Physiology at some previous Intermediate Examination carried on under the present regulations, at which examination he shall not be allowed to compete for Honours.

Candidates must produce certificates to the following effect:—1. Of having taken the degree of Bachelor of Surgery in this University.[6] 2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University, (*a*) to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division. 3 Of moral character, signed by two persons of respectability.

Fee for this degree, £5. The examination is conducted by means of printed papers and *viva-voce* interrogation.

Candidates will be examined in Mental Physiology, and in Surgery.

Doctor of Medicine.—The examination for this degree takes place once in each year, and commences on the first Monday in December.

Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University, (*a*) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Medicine in this University. One year of attendance on Clinical or Practical Medicine or two years of practice will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability.

Fee for this degree, £5.[7] The examination is conducted by means of printed papers and *viva-voce* interrogation.

Candidates will be examined in Mental Physiology and in Medicine.

UNIVERSITY OF DURHAM.

Three Licences and four Degrees in Medicine are conferred—viz., Licences in Medicine, in Surgery, and in Sanitary Science; and the Degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, and Doctor in Medicine.

For the degree of *Bachelor in Medicine* (*M.B.*) there are three professional examinations: the first being held in September (in 1887, commencing on the 19th) and April (in 1888, commencing on the 16th); the second in September (in 1887, commencing on the 26th) and April (in 1888, commencing on the 23rd; and the third in December (in 1887, commencing on the 5th) and in June (in 1888, commencing on the 11th).

The subjects for the first examination are—Elementary Anatomy and Elementary Physiology, Chemistry, with Physics, and Botany. Candidates must produce the following certificates:—(1) Of registration as a medical student. (2) Of attendance on the following courses of lectures: Anatomy, Physiology, Chemistry, with Physics, and Practical Anatomy (Dissections), each six months; Botany and Practical Chemistry, each three months.

The subjects for the second examination are Anatomy, Physiology, Materia Medica, with Pharmacy. For it the following certificates are necessary: Lectures, &c.—Anatomy, Physiology, Practical Anatomy (Dissections), second courses of six months each; Materia Medica, Practical Phy-

[6] Candidates who have obtained the degree of Bachelor of Medicine previously to 1886 will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor of Surgery; and in the case of such candidates the attendance on surgical practice required by Regulation 2 may commence from the date of the M.B. degree.

[7] This fee will continue to be £10 to all such as, having taken their M.B. degree under the former regulations, shall not have paid the fee of £5 at the Preliminary Scientific Examination.

Digitized by Google

siology, and Practical Pharmacy, courses of three months each. The candidate must also produce a certificate of his having passed the first examination for the M.B, or the first examination of the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England, together with the extra examinations in Chemistry and Botany of the University of Durham.

The subjects for the third examination are Medicine, Surgery, Pathology, Therapeutics, Midwifery and Diseases of Women and Children, Medical Jurisprudence, and Public Health. For it candidates must produce the following certificates—viz.: 1. Of being not less than twenty-one years of age. 2. Of good moral character. 3. Of having passed one of the following examinations in Arts: (*a*) the Examination for Graduation in Arts at one of the following universities—Oxford, Cambridge, Durham, Dublin, London, Queen's (Ireland), Edinburgh, Glasgow, St. Andrews, Aberdeen, Calcutta, Madras, Bombay, McGill College (Montreal), Queen's College (Kingston), Victoria (Manchester), and Royal (Ireland); or (*b*) the Preliminary or Extra-professional Examination for Graduation in Medicine at one of the following Universities—Cambridge, London, Edinburgh, Glasgow, St. Andrews, Aberdeen, Queen's (Ireland), Victoria (Manchester), and Royal (Ireland), provided that the candidate in obtaining the certificate shall have satisfied the examiners in Greek. Candidates holding a certificate which does not include Greek may offer themselves for examination in that subject alone at the examination for the certificate for Proficiency in General Education at Durham, or at the Preliminary Examination in Arts for the degrees in Medicine above mentioned. This regulation will apply to all candidates entering for the degrees in Medicine on or after October 1st, 1888; or (*c*) the Preliminary Examination in Arts qualifying for the Membership of the Royal College of Physicians of London or for the Fellowship of the Royal College of Surgeons of England; or (*d*) the Preliminary Examination in Arts for the degrees in Medicine of the University of Durham (in 1888, commencing on March 20th and Sept. 18th). 4. Of attendance on the following course of lectures—viz.: Medicine and Surgery, each two courses of six months; Public Health, one course; Forensic Medicine, Midwifery, and Diseases of Women and Children, and Pathology, each one course of three months; Clinical Medical and Clinical Surgical Lectures, each two winters and two summers; Medical Hospital Practice and Surgical Hospital Practice and Post-mortem Demonstrations, each three winters and two summers; Medical Clinical Clerking and Surgical Dressing, each six months; Clinical Obstetrics, three months; attendance on not less than twenty-one cases of Midwifery, and instruction in Vaccination.

N.B.—It is required that one of the four years of professional education shall be spent in attendance at the College of Medicine, Newcastle-on-Tyne. Candidates for the First Examination who have passed the First Examination of the Conjoint Board in England, and candidates who hold a qualification from a recognised Licensing Body in the United Kingdom, will be exempt from the First Examination of the University, except in the subjects of Chemistry, with Physics and Botany. Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board.

For the degree of *Bachelor in Surgery* (*B.S.*) every candidate must have passed the examination for the degree of Bachelor in Medicine of the University of Durham, and must have attended one course of lectures on Operative Surgery, and one course on Regional Anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of *Master in Surgery* (*M.S.*) candidates must not be less than twenty-four years of age, must have obtained the degree of Bachelor in Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Surgery in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice. The subjects of examination shall be: Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, and Clinical Surgery.

For the degree of *Doctor of Medicine* (*M.D.*) candidates must not be less than twenty-four years of age, must have obtained the degree of M.B. at least two years previously, and in the interim have been engaged in medical and surgical practice. Each candidate will be required to write an essay on some medical subject selected by himself and approved by the Professor of Medicine, and to pass an examination thereon.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the registrar of the College.

VICTORIA UNIVERSITY, MANCHESTER.

Colleges of the University: Owens College, Manchester, and University College, Liverpool.

Three degrees in Medicine and Surgery are conferred by the Victoria University—viz., Bachelor of Medicine (M.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.).

All candidates for degrees in Medicine and Surgery are required—(1) To have matriculated in the University; and (2) to pass (either *before* or *after* matriculation) an examination called the Entrance Examination in Arts, or to have passed such other examination as may be recognised by the University for this purpose.[8]

Degree of Bachelor of Medicine.—Before admission to the degree of M.B candidates are required to present certificates that they will have attained the age of twenty-one years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than four years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in a College of the University, and one year at least having been passed in a College of the University subsequently to the date of passing the Preliminary Examination in Science. All candidates for the degree of Bachelor of Medicine are required, after matriculating, to satisfy the examiners in the several subjects of the following examinations: the Preliminary Examination in Science, the Intermediate Examination for the degree of M.B., and the Final Examination for the degree of M.B.

The Preliminary Examination in Science.—The subjects of examination are as follows:—1. Chemistry. 2. Elementary Biology. 3. Physics. Candidates for the Preliminary Examination in Science must have attended during at least one year courses, both of lectures and of laboratory work, in each of the above-named subjects.

The Intermediate M.B. Examination.—The subjects of examination are as follows:—1. Anatomy. 2. Physiology (including Physiological Chemistry and Histology). 3. Materia Medica and Pharmacy. Candidates for the Intermediate M.B. Examination are required to have passed the Preliminary Examination in Science, and to have attended courses of instruction in Anatomy for one winter session, in Physiology for two winter sessions (but one session will be accepted provided that a full course has been attended by the candidate), and in Materia Medica and Pharmacy for one summer session. The certificates must show (1) that the human body has been dissected twice at least; (2) that laboratory instruction has been received in Physiology; (3) that practical instruction has been received in Materia Medica and Pharmacy.

The Final M.B. Examination.—The examination is divided into two parts, called the First Part and the Second Part respectively, which may be passed separately or on the same occasion, but the First Part cannot be taken before the end of the third year, and the Second Part cannot be taken before the end of the fourth year, of medical study in accordance with the University Regulations. The subjects of examination are as follows:—Part I.: 1. Systematic Surgery. 2. Pharmacology and Therapeutics. 3. General Pathology. Part II.: 1. Systematic and Clinical Medicine, including Mental Diseases. 2. Practical and Clinical Surgery. 3. Obstetrics and Diseases of Women and Children. 4. Morbid Anatomy. 5. Forensic Medicine. 6. Hygiene.

Candidates, before presenting themselves for the Final Examination, are required to have passed the Intermediate Examination, and to furnish certificates—1. Of having

[8] The Examinations at present recognised are:—1. The Preliminary Examination of the Victoria University, provided Latin and Mechanics have been taken up. 2. The Matriculation Examination of the University of London. 3. The Previous Examination of the University of Cambridge. 4. Responsions and Moderations of the University of Oxford. 5. The Leaving Certificate Examination of the Oxford and Cambridge Boards, provided that it include Latin, English, Mathematics, and Elementary Mechanics. 6. The Final Examination for Graduation in Arts of any University in Great Britain and Ireland.

Digitized by Google

attended the Medical and Surgical Practice of a hospital or hospitals, approved by the University, during at least three years, of which years two at least must be subsequently to the date of passing the Intermediate Examination, except when exemption has been granted by the General Board of Studies, after report from the Departmental Board of Medical Studies. 2. Of having attended during at least twelve months demonstrations in the post-mortem theatre of a hospital. 3. Of having attended, under proper supervision, at least twenty cases of labour. 4. Of having during at least three months received in either a general or a special hospital, approved by the University, such Clinical Instruction in the Diseases peculiar to Women as shall be approved by the University. 5. Of having acquired proficiency in Vaccination. 6. Of having attended courses of instruction, approved by the University, in a College of the University or in a College or Medical School recognised for this purpose by statute of the University, in the following subjects:—(*a*) Systematic Medicine, (*b*) Clinical Medicine, (*c*) Systematic Surgery, (*d*) Practical Surgery, (*e*) Clinical Surgery, (*f*) Obstetrics and Diseases of Women and Children, (*g*) Pharmacology and Therapeutics, (*h*) General Pathology and Morbid Anatomy, (*i*) Forensic Medicine, (*j*) Hygiene.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degree of Bachelor of Medicine, and at least one year has elapsed since they passed the examination for that degree. Candidates for the degree of Doctor of Medicine are required to present a printed dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine. No candidate will be admitted to the degree unless his dissertation, after report from the Departmental Board of Medical Studies, shall have been recommended by the General Board of Studies to the Council for acceptance in that behalf. Candidates may be examined on any subject connected with their dissertations.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degree of Bachelor of Medicine, and at least one year has elapsed since they passed the examination for that degree.

The subjects of examination are as follows: (1) Surgical Anatomy; (2) Surgical Pathology; (3) Practical Surgery, including the performance of operations on the dead body; (4) Clinical Surgery; (5) Ophthalmology.

UNIVERSITY OF EDINBURGH.

Three medical degrees are conferred by the University of Edinburgh—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The degree of Master in Surgery is not conferred on any person who does not also at the same time obtain the degree of Bachelor of Medicine.

No one is admitted to the degrees of Bachelor of Medicine and Master in Surgery who has not been engaged in medical and surgical study for four years—the medical session of each year, or *annus medicus*, being constituted by at least two courses of not less than one hundred lectures each, or by one such course and two courses of not less than fifty lectures each; with the exception of the clinical courses, in which lectures are to be given at least twice a week during the prescribed periods.[9]

Every candidate for the degree of M.B. and C.M. must give sufficient evidence by certificates—(*a*) That he has studied each of the following departments of medical science, namely, Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Children, and General Pathology, each during courses including not less than one hundred lectures; Practical Anatomy, a course of the same duration as those of not less than one hundred lectures;[10] Practical Chemistry, three months; Practical Midwifery, three months at a midwifery hospital, or a certificate of attendance on six cases from a registered medical practitioner; Clinical Medicine, Clinical Surgery,[11] courses of the same duration as those of not less than one hundred lectures, or two courses of three months' lectures, being given at least twice a week; Medical Jurisprudence, Botany, Natural History (including Zoology), during courses including not less than fifty lectures. (*b*) That he has attended, for at least two years, the medical and surgical practice of a general hospital which accommodates not fewer than eighty patients, and possesses a distinct staff of physicians and surgeons. (*c*) That he has attended, during a course of not less than fifty hours' instruction, the class of Practical Materia Medica in the University of Edinburgh, or a similar class conducted in a university or recognised school of medicine, or a similar class conducted at the laboratory of a hospital or dispensary, or elsewhere, by a teacher recognised by the University Court under Section VI. Sub-section 4; or that he has been engaged by apprenticeship for not less than two years with a registered medical practitioner, or a member of the Pharmaceutical Society of Great Britain, or a member of the Pharmaceutical Society of Ireland, or a pharmaceutical chemist, or chemist and druggist, registered under the provisions of the "Act for regulating the qualifications of pharmaceutical chemists, 1852," "The Pharmacy Act, 1868," or "The Pharmacy Act (Ireland), 1875," in the *bonâ fide* compounding and dispensing of drugs, and the preparation of their officinal and other preparations under his superintendence. (*d*) That he has attended, for at least six months, by apprenticeship or otherwise, the out-door practice of a hospital, or the practice of a dispensary physician, a surgeon, or a member of the London or Dublin Society of Apothecaries. (*e*) That he has attended, during courses of not less than fifty hours' instruction, classes of Practical Physiology and Practical Pathology in the University of Edinburgh, or in a university or school of medicine recognised by Sub-sections 2 and 4 of Section VI. of Ordinance No. 8, Edinburgh No. 3, or upon classes thereof, conducted by a teacher recognised by the University Court under the said Sub-section 4.

Students of Medicine in the London schools, and in the school of the College of Surgeons in Dublin, can obtain there two *anni medici* out of the four required for the Edinburgh degrees in Medicine. Courses of lectures in these schools, and the courses of the medical teachers and of the science teachers in King's College and in University College, London, in the subjects of graduation, are regarded as equivalent to lectures on the corresponding subjects in this University, except Materia Medica and Midwifery, which when only three months' courses are not received as equivalent. One *annus medicus* may be constituted by attendance on Practical Anatomy and Hospital Practice during the winter session. Another *annus medicus* by attending either (*a*) full winter courses on any two of the following subjects—Anatomy, Physiology, Chemistry, Pathology, Surgery, Medicine, Clinical Surgery, Clinical Medicine; or (*b*) on one such course and two three months' courses on any of the following subjects—Botany, Practical Chemistry, Natural History, Medical Jurisprudence. If the student selects the arrangement prescribed in (*a*), attendance on a third course, although unnecessary to constitute an *annus*, will also be accepted. The other subjects and the additional courses, not given in London or Dublin, necessary for the degrees of the University, require to be attended at this University. In provincial schools, where there are no lecturers recognised by the University Court, a candidate can only have one *annus medicus*, and this is constituted by attendance at a qualified hospital along with a course of Practical Anatomy. But in a provincial school where there are two or more lecturers recognised by this University, a second *annus medicus* may be made by attendance on at least two six months', or one six months' and two three months', recognised courses.

Every candidate must deliver, before the 31st day of March of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine a declaration in his own handwriting that he has completed his twenty-first year, or that he will have done so on or before the day of graduation, and that he will not be on the day of graduation under articles of apprenticeship to any surgeon or other master. This declaration, along with a statement of studies, accompanied with proper certificates, is appended to the schedule for the Final Examination, and must be signed before the schedule is given in.

[9] [redacted] of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least one hundred lectures, or fifty lectures in conformity with the requirements of this section. Three months' courses on Materia Medica, Pathology, and Midwifery do not qualify.

[10] The certificate of attendance on Practical Anatomy must express not only the number of months engaged in dissection, but the names of the [redacted] and the degree of care with which the dissections have been conducted. Candidates are recommended not to appear for an examination [redacted] with a view to a degree until they have dissected the [redacted] body at least once.

[11] The Medical Faculty recommend that medical students should not attend Clinical Surgery during their first six months' attendance on Clinical Medicine.

Digitized by Google

Each candidate is examined, both in writing and orally, on Chemistry, Botany, and Natural History; on Anatomy, Institutes of Medicine, Materia Medica (including Practical Pharmacy), and Pathology; on Surgery, Practice of Medicine, Midwifery, and Medical Jurisprudence; clinically, on Medicine and on Surgery in a hospital. The examinations on Anatomy, Chemistry, Institutes of Medicine, Botany, Natural History, Materia Medica, and Pathology are conducted, as far as possible, by demonstrations of objects placed before the candidates. Students who have passed their examination on the first division of these subjects may be admitted to examination on the second division at the end of their third year. The examination on the third and fourth divisions cannot take place until the candidate has completed his fourth *annus medicus*. Candidates may, if they choose, be admitted to examination on the first two of these divisions at the end of their third year, or to the four examinations at the end of their fourth year.

The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of Bachelor of Medicine and Master in Surgery, and who is of the age of twenty-four years, and produces a certificate of having been engaged, subsequently to his having received the degrees of M.B. and C.M., for at least two years in attendance on a hospital, or in the military or naval medical service, or in medical and surgical practice; provided always that the degree of M.D. shall not be conferred on any person unless he be a graduate in Arts of one of the universities of England, Scotland, or Ireland, or of such other universities as are above specified, or unless he shall, before or at the time of his obtaining the degrees of M.B. and C.M., or thereafter, have passed a satisfactory examination on *three* of the subjects mentioned in Section II. of the statutes relative to preliminary examination. Two of these must be Greek and Logic or Moral Philosophy, and the third is to be one of the following subjects, at the option of the candidate—namely, French, German, Higher Mathematics, and Natural Philosophy; and provided also that the candidate for the degree of M.D. shall submit to the Medical Faculty a thesis, certified by him to have been composed by himself, and which shall be approved by the Faculty, or any branch of knowledge comprised in the professional examinations for the degrees of M.B. and C.M., which he may have made a subject of study after having received that degree.

The fees for M.B. and C.M. are £22. Total fees and stamp for graduating as M.D. only, by regulations for students commencing before February, 1861, £25. The fees for examination must be paid at the secretary's office ten days before the dates thereof, and the fees for the degree of M.D. and the stamp duty for the latter must be paid on or before the 15th day of July in the year of graduation. In the event of the candidate not passing any one of the professional examinations, the fee is not returned; but he may appear at one subsequent examination without paying an extra fee, and at any future examination on paying one-half the fee.

UNIVERSITY OF GLASGOW.

Three degrees in Medicine are granted—viz., Bachelor of Medicine, Master in Surgery, and Doctor of Medicine. The curricula of study and the examinations for the several degrees conferred are nearly the same as in the University of Edinburgh. The annual term for conferring medical and surgical degrees is the 1st of August. The Preliminary Examinations of medical students in branches of general education begin on the 5th of October, 1887, and on the 28th of March, 1888.

The fees for the degrees are £21 for M.B. and C.M., which are obtained together, and £15 for M.D.

The regulations under which the above degrees are granted and the notices of the subjects of examination may be obtained by application to the assistant-clerk, Matriculation Office, the University.

The first, second, and third Professional Examinations are held in April and in October each year, and the fourth or final examination is held annually in June and July.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the University of Edinburgh.

Professional Examinations will be held twice in each year—namely, in April and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1; summer session alone, 10*s*.

Candidates who commenced their medical studies before November, 1861, are entitled to appear for examination for the degree of M.D. after four years' study, one of which must have been in the University of Aberdeen.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: Sick Children's Hospital; General Dispensary, and Lying-in and Vaccine Institutions, daily; Royal Lunatic Asylum; Eye Institution, in which is given clinical instruction on the Diseases of the Eye, and on the application of the Ophthalmoscope for their diagnosis.

Regulations for the Diploma in Public Health (D.P.H.).—Candidates for the diploma must have graduated in Medicine in the University before they receive the diploma; and they must give evidence of having attended a course of instruction in Analytical Chemistry or in Practical Hygiene. The diploma is conferred after an examination in Public Health, held in March and July of each year. Candidates desiring to appear for examination at either of these periods must send their names, with the necessary fee, to the Secretary of the Medical Faculty before the first day of the month in which the examination takes place. The fee for the examination is 3 guineas. In the event of a candidate failing to pass the examination, a fee of 1 guinea will be charged for each subsequent examination for which he may enter. The examination is conducted by the examiners for the medical degrees. The examination is written, oral, and practical. The subjects and scope of the examination are as follows:—1. Physics and Meteorology: The general principles of Physics in so far as they relate to Heat and Ventilation, Water Supply and Drainage. The elements of Meteorology and Climatology. Practical exercises in the use of Meteorological Instruments. 2. Chemistry and Microscopy: The Composition and Analysis of Air, Water, and Sewage; the Composition and Adulterations of the more common Foods and Beverages; Diseased and Putrid Food. Practical exercises in the Chemical and Microscopical examination of Air, Water, and Foods. 3. General Hygiene: Duties of Medical Officers of Health; Nature and Construction of Dietaries; Construction and Sanitary Arrangements of Houses, Hospitals, Workshops, Factories, Towns, &c., including interpretation of plans; Ventilation, Water Supply, Sewerage, Disposal of Dead; Etiology, Prophylaxis (including Vaccination), and Control of Infectious Diseases; Unhealthy Occupations. Practical exercises in examining and reporting on the Construction and Sanitary Arrangements of Houses, &c. 4. Sanitary Law and Vital Statistics: Laws relating to the Public Health of Scotland, England, or Ireland, at the option of the candidate. Laws relating to Vaccination, and Registration of Births, Marriages, and Deaths. Methods and Data of Vital Statistics, mainly in so far as they relate to the birth, marriage, and death rate of communities.

Application for further information should be addressed to the Dean of the Medical Faculty.

A diploma in Public Health is granted by the University to its Graduates in Medicine, after a special examination. The diploma can be entered on the Register of the General Medical Council. The Regulations can be obtained on application to the Dean.

UNIVERSITY OF ST. ANDREWS.

Two degrees in Medicine are granted—namely, Bachelor of Medicine and Master in Surgery (M.B., C.M.), and Doctor of Medicine (M.D.). The curricula for these degrees, and the regulations under which they are conferred, differ from those of the University of Edinburgh only in the particulars noticed below.

The degree of *Doctor of Medicine* may be conferred by the University of St. Andrews on any registered medical practitioner above the age of forty years whose professional position and experience are such as, in the estimation of the University, to entitle him to that degree, and who shall, on examination, satisfy the medical examiners of the sufficiency of his professional knowledge; provided always that degrees will not be conferred under this section on a greater number than ten in any one year. The examinations are held yearly towards the end of April. Candidates must lodge with the Dean of the Medical Faculty the following certificates, along with application for admission to examination:—1. A cer-

Digitized by Google

tificate of age. being a baptismal certificate or an affidavit of age. 2. Holograph certificates from at least three medical men of acknowledged reputation in the medical profession or in the medical schools, recommending the candidate to the Senatus for the degree, and testifying to his professional skill and position. As only ten can graduate yearly, candidates will be selected whose service and certificates seem to the Medical Faculty to present the highest professional claims; and where these seem equal, preference will be given to age and priority of application. 3. A portion of the graduation fee (viz., £10 10*s.*) shall be forfeited should the candidate fail to appear or to graduate at the time appointed. A satisfactory examination, written and *viva voce*, must be passed in the following departments—viz, Materia Medica and General Therapeutics, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, Midwifery, and Diseases of Women and Children.

No one will be received as a candidate for the degree of *Bachelor of Medicine and Master in Surgery* unless two years at least of his four years of medical and surgical study shall have been in one or more of the following universities or colleges—viz.. the Universities of St. Andrews, Glasgow, Aberdeen, Edinburgh, Oxford, and Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

Subject always to the condition here specified, the studies for candidates for the degree of Bachelor of Medicine and Master in Surgery will be under the following regulations. The remaining years of medical and surgical study may be either in one or more of the universities and colleges above specifird, or in the hospital schools of London, or in the school of the College of Surgeons of Dublin, or under such private teachers of medicine as may from time to time receive recognition from the University Court. Attendance during at least six winter months on the medical or surgical practice of a general hospital which accommodates at least eighty patients, and during the same period on a course of Practical Anatomy, may be reckoned as one of such remaining years.

Every candidate for examination for the degree of M.B. and C.M. is required to lodge a declaration of age, a statement of his course of study, his inaugural dissertation, and all his certificates with the Dean of the Medical Faculty, on or before the 25th of March in each year.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5*s.* is payable. No student can be admitted for the winter course after Nov. 25th.

Previous Medical Examination.—Candidates for degrees and licences in Medicine and Surgery are required to pass an examination in Physics, Chemistry, Botany, Comparative Anatomy, Descriptive Anatomy, and Institutes of Medicine (Practical Histology and Physiology) previously to their degree examination.

Bachelor in Medicine.—A candidate for this degree must be a graduate in Arts, and may obtain the degree of Bachelor in Medicine at the same Commencements as that at which he receives his degree of B.A., or at any subsequent Commencements. The medical education of a Bachelor in Medicine is of four years' duration, and comprises attendance on a single course of each of the following lectures—Anatomy, Practical Anatomy, Theory of Surgery, Chemistry, Materia Medica and Pharmacy, Physiology, Practice of Medicine, Midwifery, Botany, Medical Jurisprudence, Heat, Electricity, Magnetism, Comparative Anatomy; three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other metropolitan hospital recognised by the Board of Trinity College; six months' instruction in Practical Midwifery, including Clinical Lectures; a certificate of personal attendance on Fever cases, with names and dates of cases. Six months' dissections, three months' laboratory instruction in Chemistry, three months' Practical Histology, and one month's instruction in Vaccination are required. Any of the above-named courses may be attended at any medical school in Dublin recognised by the Provost and Senior Fellows. Fee for the *Liceat ad Examinandum*, £5; for the M.B. degree, £11.

Doctor in Medicine.—A Doctor in Medicine must be M.B. of not less than three years' standing, or have been qualified to take the degree of M.B. for three years, and must read a thesis or undergo an examination before the Regius Professor of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this degree, £13.

Bachelor in Surgery.—A Bachelor in Surgery must be a Bachelor in Arts and in Medicine, and have spent four years in the study of Surgery and Anatomy. He must also pass a public examination in the Hall before the Professors of the School of Physic, having previously completed the prescribed curriculum of study, which includes the following additions to the courses named above for the M.B.: Operative Surgery, Two Courses of Dissections, Ophthalmic Surgery.[12] Candidates are required to perform surgical operations on the dead subject. Fee for the *Liceat ad Examinandum*, £5; for the degree of Bachelor in Surgery, £5.

Master in Surgery.[13]—A Master in Surgery must be a Bachelor in Surgery of three years' standing, or have been qualified to take the degree of Bachelor in Surgery for three years; and must read a thesis publicly before the Regius Professor of Surgery, or undergo an examination before the Regius Professor, according to regulations to be approved by the Provost and Senior Fellows. Fee for the degree of Master in Surgery, £11.

University Licences.—Candidates for the Licences in Medicine or Surgery must be matriculated in Medicine, and must have completed two years in Arts and four years in medical studies.

Licentiate in Medicine.—The medical course and examination necessary for the licence in Medicine are the same as for the degree of M.B. Fee for the *Liceat ad Examinandum*, £5; for the licence in Medicine, £5.

Licentiate in Surgery.—The surgical course and examination necessary for the licence in Surgery are the same as for the degree of Bachelor in Surgery. Fee for the *Liceat ad Examinandum*, £5; for the licence in Surgery, £5.

The total cost of the education and first degrees in Medicine and Surgery is as follows, in addition to the fees for education in Arts and B.A. degree (£83 4*s.*): Medical and Surgical Lectures, £60 12*s.* 6*d.*; Hospitals, £44 2*s.*: Medical and Surgical Examinations and Degrees, £26.

ROYAL UNIVERSITY OF IRELAND.

The following degrees are conferred by the University in this Faculty: Bachelor of Medicine. Doctor of Medicine, Master of Surgery, Master of Obstetrics; in Sanitary Science, a special diploma. All the medical examinations are held twice yearly—viz., towards the end of April and in October.

The course for degrees in Medicine &c. is one of at least four years' duration. Students who have commenced their medical studies since January 1st, 1884, must also produce a certificate of having been registered as students in Medicine by the Medical Council for a period of at least forty-five months. No one can be admitted to any degree in Medicine who is not fully twenty-one years of age. All candidates for these degrees are, in addition to attending the lectures and complying with the other conditions to be from time to time prescribed, required to pass the following examinations: the Matriculation Examination, the First University Examination, the First Examination in Medicine, the Second Examination in Medicine, and the Degree Examination.

The First Examination in Medicine.—Students are admitted to this examination after the lapse of one academical year from the time of their matriculation. The subjects of this examination are—Zoology, Botany, and a modern language (either French or German). Candidates who have passed in a modern language at the First University Examination in Arts are exempt from again presenting this subject at the First Examination in Medicine, except as a qualification for admission to compete for Honours, the answering of the candidates in the three subjects above mentioned being taken into account in awarding Honours.

The Second Examination in Medicine.—Students are admitted to this examination after the lapse of one academical year from the time of passing the First Examination in Medicine, provided they have completed the First Period of the Course of Medical Studies. The subjects of this exami-

[12] Students in the School of Physic who matriculated before June 22nd, 1872, may obtain the degree of Master in Surgery according to the regulations in force previously to the creation of the degree of Bachelor in Surgery.

[13] Masters in Surgery must be of the standing of Master of Arts.

Digitized by Google

nation are—Anatomy, Physiology, Materia Medica (Pharmacology), and Chemistry.

The Examination for the Degree of M.B.—Students are admitted to this examination after the lapse of one academical year from the time of passing the Second Examination in Medicine, provided they have completed the Second Period of the Course of Medical Studies. The subjects of this examination are—Anatomy, including Practical Anatomy; Physiology, including Practical Physiology and Histology; Surgery, Midwifery, and Diseases of Women and Children; Pathology; Vaccination; Theory and Practice of Medicine, Medical Jurisprudence; Mental Diseases; Hygiene.

M.D. Degree.—Candidates may be admitted to this degree after the lapse of two academical years from the time of obtaining the degree of M.B.; provided, however, that all persons who were students in Medicine in the Queen's University at the date of its dissolution shall be entitled, if they so desire, to obtain the degree of M.D., instead of the degree of M.B., upon passing the examination herein prescribed for the M.B. degree. Every candidate will be examined at the bedside, and required to diagnose at least six cases, medical and surgical, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners, and to discuss all the questions arising thereon. Every candidate must submit to the medical examiners, for their approval, a thesis certified by him (or her) to have been composed by himself (or herself). No thesis will be approved which does not contain some original or personal observations in Practical Medicine, Surgery, Midwifery, or in some of the sciences embraced in the curriculum, or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted.

The *M.Ch. Degree* will be conferred only on graduates in Medicine of the University. The examination will comprise the Theory and Practice of Surgery, including Operative and Clinical Surgery.

The *M.A.O. Degree* will also be conferred only on graduates in Medicine of the University. The examination will comprise the Theory and Practice of Midwifery, and the use of Obstetrical Instruments and Appliances. Candidates will be required to undergo a special written examination in Midwifery, Gynæcology, and Diseases of Children, in addition to the other tests.

Diploma in Sanitary Science.—This diploma will be conferred only on graduates in Medicine of the University. Candidates must give notice in writing to the secretaries of their intention to present themselves, and must pay the prescribed fee of £2 at least one month previously to the examination. The examination will include the following subjects:—Physics, Climatology, Chemistry, Geology, Sanitary Engineering, Hygiene, Sanitary Law, and Vital Statistics. Proficiency in practical work and an adequate acquaintance with the instruments and methods of research which may be employed for hygienic investigations are indispensable conditions of passing the examination.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

The licence of this College is a qualification to practise Medicine, Surgery, and Midwifery, and is recognised by the Local Government Board as a qualification in Surgery as well as in Medicine.

Licentiates.—Every candidate for the College licence (except when otherwise provided by the bye-laws) is required to produce satisfactory evidence to the following effect:—Of having attained the age of twenty-one years. Of moral character. Of having passed before the commencement of professional study an examination in the subjects of general education recognised by the General Medical Council. Of having been registered as a medical student in a manner prescribed by the General Medical Council. Of having been engaged in professional studies during at least forty-five months, of which at least three winter sessions and two summer sessions shall have been passed at a recognised medical school or schools, and one winter session and two summer sessions in one or other of the following ways:—1. Attending the practice of a hospital or other institution recognised by the College for that purpose; 2. Receiving instruction as the pupil of a legally qualified practitioner having opportunities of imparting a practical knowledge of Medicine, Surgery, or Midwifery; 3. Attending lectures on any of the required subjects of professional study at a recognised place of instruction. Of having attended, during three winter sessions and two summer sessions, the medical and surgical practice at a recognised hospital or hospitals.[14] Of having discharged the duties of a medical clinical clerk during six months, and of a surgical dresser during other six months; and of having been engaged during six months in the clinical study of Diseases peculiar to Women. Of having received instruction in Chemistry, Practical Chemistry, Materia Medica, and Practical Pharmacy. Of having attended a course of lectures on the following subjects:—Anatomy (with dissections), during twelve months; Physiology; a practical course of General Anatomy during a winter or a summer session, consisting of not less than thirty meetings of the class; Pathological Anatomy; Principles and Practice of Medicine; Principles and Practice of Surgery; Midwifery and the Diseases peculiar to Women; Forensic Medicine. Of having attended Clinical Lectures on Medicine during nine months, and also Clinical Lectures on Surgery during nine months, and of having been engaged during a period of three months in the Clinical Study of Diseases peculiar to Women. Of having passed the professional examinations, of which there are three, each partly written, partly oral, and partly practical. The subjects of the first examination are: Chemistry, including Chemical Physics—viz., Heat, Light, and Electricity; Materia Medica and Pharmacy; and Osteology. The subjects of the second examination are Anatomy and Physiology. The subjects of the final examination are: Medical Anatomy and Pathology, including Morbid Anatomy; the Principles and Practice of Medicine; Surgical Anatomy and Pathology, including Morbid Anatomy; the Principles and Practice of Surgery; Midwifery and Diseases peculiar to Women; Forensic Medicine; Public Health and Therapeutics.

Any candidate who shall produce satisfactory evidence of having passed an examination on Anatomy and Physiology, conducted by a university in the United Kingdom, in India, or in a British colony, or by the College of Surgeons in England, Scotland, or Ireland, or the Faculty of Physicians and Surgeons of Glasgow, shall be exempt from re-examination on those subjects. Any candidate who shall produce satisfactory evidence of having passed an examination on Chemistry and Materia Medica, required for a degree in Medicine at a university in the United Kingdom, in India, or in a British colony, will be exempted from re-examination on those subjects. Any candidate who shall have obtained a degree in Surgery at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, after a course of study and an examination satisfactory to the College, shall be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

REGULATIONS RESPECTING THE EDUCATION AND EXAMINATIONS APPLICABLE TO CANDIDATES FOR THE DIPLOMA OF MEMBER OF THE COLLEGE.

Professional Examination.—The following are recognised modes of commencing professional education:—(1) Attendance on the practice of a hospital, or other public institution recognised by this College for that purpose. (2) Instruction as the pupil of a legally qualified surgeon, holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council. (3) Attendance on lectures on Anatomy, Physiology, or Chemistry, by lecturers recognised by this College.

Candidates, prior to their admission to the First or Primary Examination on Anatomy and Physiology, will be required to produce the following certificates—viz.: Of having, prior to the commencement of professional study, been registered by the General Medical Council. Of having attended lectures

[14] A three months' course of clinical instruction in the wards of a recognised lunatic hospital or asylum may be substituted for the same period of attendance in the medical wards of a general hospital.

Digitized by Google

on Anatomy during two winter sessions. Of having performed dissections during not less than two winter sessions. Of having attended lectures on General Anatomy and Physiology[15] during one winter session. Of having attended a practical course of General Anatomy and Physiology[16] during another winter or a summer session, consisting of not less than thirty meetings of the class.

Candidates who commenced their professional studies on or after October 1st, 1882, and shall have pursued those studies in recognised medical schools in England, will be required, before presenting themselves for the Primary or Anatomical and Physiological Examination for the diploma of Member of the College, to produce certificates of having passed an examination in Elementary Anatomy and Physiology, such examination to be conducted by their teachers at the several medical schools. (1) The periods at which the examinations shall be held will be determined by the teachers at the several medical schools, provided that an interval of not less than six months shall elapse between the date at which the candidates shall have passed the examination and the date of their presenting themselves for the Primary Examination at the College. (2) It shall be left to the teachers at the several medical schools to determine the nature and extent of the examination in Elementary Anatomy and Physiology.

Candidates, prior to their admission to the Second or Pass Examination on Surgical Anatomy and the Principles and Practice of Surgery, Medicine, and Midwifery, will be required to produce the following certificates—viz.: Of being twenty-one years of age. Of having been engaged, subsequently to the date of registration by the General Medical Council, during four years, or during a period extending over not less than four winter and four summer sessions, in the acquirement of professional knowledge. Of having attended lectures on Surgery during one winter session. Of having attended a course of Practical Surgery during a period occupying not less than six months prior or subsequent to the course required by the preceding Clause 3.[17] Of having attended one course of lectures on each of the following subjects—viz.: Chemistry,[18] Materia Medica, Medicine, Forensic Medicine, Midwifery (with practical instruction), and a certificate of having personally conducted not less than ten labours, and Pathological Anatomy during not less than three months. Of having studied Practical Pharmacy during three months. Of having attended a three months' course of Practical Chemistry (with manipulations), in its application to medical study.[19] Of instruction and proficiency in the practice of Vaccination.[20] Of having attended, at a recognised hospital or hospitals, the Practice of Surgery, during three winter[21] and two summer[22] sessions. Of having been individually engaged, at least twice in each week, in the observation and examination of patients at a recognised hospital or hospitals, under the direction of a recognised teacher, during not less than three months.[23] Of having, subsequently to the first winter session of attendance on Surgical Hospital Practice, attended at a recognised hospital or hospitals, Clinical Lectures on Surgery, during two winter and two summer sessions. Of having been a dresser at a recognised hospital, or of having, subsequently to the completion of one year's professional education, taken charge of patients under the superintendence of a surgeon during not less than six months, at a hospital, general dispensary, or parochial or union infirmary recognised for this purpose, or in such other similar manner as, in the opinion of the Council, shall afford sufficient opportunity for the acquirement of Practical Surgery. Of having attended during the whole period of attendance on Surgical Hospital Practice (see Clause 9) demonstrations in the post-mortem rooms of a recognised hospital. Of having attended, at a recognised hospital or hospitals, the Practice of Medicine, and Clinical Lectures on Medicine, during one winter and one summer session.

Special Notice.—Candidates commencing their professional education on or after the 1st of October, 1882, will not be admitted to the Second or Pass Examination until after the expiration of two years from the date of their passing the Primary or Anatomical and Physiological Examination for such diploma, except in the following cases:—When a candidate, before presenting himself for the Primary Examination, shall possess a recognised degree or diploma in Medicine or Surgery, or shall have completed the curriculum of professional education for the diploma. In the case of a candidate who, being desirous of obtaining the Fellowship, shall fail to present himself for the Primary Examination for the Membership at the end of his second year of professional study, but who shall pass at the end of his third winter session the Primary Examination for the Fellowship, it being required in such case that not less than one year of attendance on the Surgical Practice of a recognised hospital shall intervene between the date of his passing the Primary Examination for the Fellowship and the date of his presenting himself for the Second or Pass Examination for the diploma of Member. In the case of a candidate who, having commenced his professional studies by attendance on the practice of a recognised provincial or colonial hospital, and having completed a year of such attendance, shall fail to pass the Primary Examination at the end of his second winter session of attendance at a recognised medical school, provided that in his case not less than one year shall elapse between the date of his passing the Primary Examination and the date of his presenting himself for the Second or Pass Examination for the diploma of Member. When a candidate, owing to illness, duly certified by one or more of the teachers of his medical school, shall be prevented from presenting himself for the Primary Examination on the completion of his second year of professional study. And in the case of a candidate who, from some unforeseen circumstances, shall fail to present himself for the Primary Examination on the completion of his second year of professional study, it being left to the Court of Examiners to determine whether in such case the candidate shall or shall not be required to comply with the regulation.

Certificates of attendance upon the practice of a recognised provincial or colonial hospital unconnected with, or not in convenient proximity to, a recognised medical school will not be received for more than one winter and one summer session of the hospital attendance required by the regulations of this College. Those candidates who shall have pursued the whole of their studies in Scotland or Ireland will be admitted to examination upon the production of the several certificates required respectively by the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the College of Surgeons in Ireland from candidates for their diploma, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied subsequently to the date of registration by the General Medical Council, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge; and in the case of candidates who shall have pursued the whole of their studies at recognised foreign or colonial universities, upon the production of the several certificates required for their degree by the authorities of such universities, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four years, or during a period extending over four winter and four summer sessions, in the acquirement of professional knowledge.

[15] By the Practical Course referred to in Clause 5, it is meant that the learners themselves shall, individually, be engaged in the necessary experiments, manipulations, &c.; but it is not hereby intended that the learners shall perform vivisections.

[16] The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

[17] The course of Practical Surgery referred to in Clause 4 is intended to embrace instruction in which each pupil shall be exercised in practical details, such as in the application of anatomical facts to surgery, on the living person or on the dead body; the methods of proceeding and the manipulations necessary in order to detect the effects of diseases and accidents on the living person or on the dead body; the performance, where practicable, of the operations of surgery on the dead body; the application of surgical apparatus; the examination of diseased structures as illustrated in the contents of a museum of morbid anatomy and otherwise.

[18] The course of lectures on Chemistry included in Clause 5 will not be required in the case of a candidate who shall have passed a satisfactory examination in this subject in his preliminary examination.

[19] The certificates of attendance on the several courses of lectures must include evidence that the student has attended the practical instructions and examinations of his teacher in each course.

[20] The certificate of instruction in vaccination must be such as will qualify the holder to contract as a Public Vaccinator under the Regulations for the time in force of the Local Government Board.

[21] The winter session comprises a period of six months, and, in Edinburgh, commences on the 1st of October and terminates on the 31st of March.

[22] The summer session comprises a period of three months, and, in Edinburgh, commences on the 1st of May and terminates on the 31st of July.

[23] It is intended that the candidate should receive the instruction required by Clause 10 at an early period of his attendance at the hospitals.

Professional Examination.—This examination is divided into two parts. The First or Primary Examination, on Anatomy and Physiology, is partly written and partly demonstrative on the recently dissected subject, and on prepared parts of the human body. The Second or Pass Examination, on Surgical Anatomy and the Principles and Practice of Surgery, Medicine, and Midwifery,[24] is partly written, partly oral, and partly on the practical use of surgical apparatus and the practical examination of patients.

The Primary Examinations are held in the months of January, April, July, and October, and the Pass Examinations in the months of January, April, July, and October. Candidates will not be admitted to the Primary Examination until after the termination of the second winter session of their attendance at a recognised school or schools; nor to the Pass or Surgical Examination until after the termination of the fourth year of their professional education. The fee of £5 5*s.*, paid prior to the first admission to the Primary Examination, is retained whether the candidate pass or fail to pass the examination, but is allowed as part of the whole fee of £22[25] payable for the diploma. A candidate, after failure at any Primary Examination, is required, on admission to any subsequent Primary Examination, to pay a further fee of £3 3*s.*, which is retained, whether he pass or fail to pass the examination, and which further fee is not allowed as part of the whole fee of £22 for the diploma.

The fee of £16 15*s.* is payable prior to each admission to the Pass Examination; but on each occasion of failure the balance of £11 10*s.* is returned to the candidate. A candidate, having entered his name for either the Primary or Pass Examination, who shall fail to attend, will not be allowed to present himself for examination within the period of three months from the date at which he shall have failed so to attend. A candidate referred on the Pass Examination is required, unless the Court of Examiners shall otherwise determine, to produce, prior to his admission to re-examination, a certificate of at least six months' further attendance on the surgical practice of a recognised hospital, together with lectures on Clinical Surgery, subsequently to the date of his reference.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

Regulations relating to the several Examinations applicable to Candidates who commenced their Professional Education on or after the 1st of October, 1884.

Any candidate who desires to obtain both the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to comply with the following regulations, and to pass the examinations hereinafter set forth. Every such candidate who shall commence professional study on or after Oct. 1st, 1884, will be required, at the times prescribed for the respective examinations, to produce satisfactory evidence—1. Of having been registered as a Medical student by the General Medical Council. 2. Of having been engaged in professional studies at least forty-five months, during which not less than three winter sessions and two summer sessions shall have been passed at one or more of the medical schools recognised by the two Colleges. 3. Of having received instruction in the following subjects: (*a*) Chemistry, including Chemical Physics, meaning thereby Heat, Light, and Electricity; (*b*) Practical Chemistry; (*c*) Materia Medica; (*d*) Pharmacy. 4. Of having performed Dissections at a recognised medical school during not less than twelve months. 5. Of having attended at a recognised medical school—(*a*) a course of lectures on Anatomy during not less than six months, or one winter session; (*b*) a course of lectures on General Anatomy and Physiology during not less than six months, or one winter session; (*c*) a separate practical course of General Anatomy and Physiology during not less then three months. 6. Of having attended at a recognised medical school—(*a*) a course of lectures on Medicine during not less than six months, or one winter session; (*b*) a course of lectures on Surgery during not less than six months, or one winter session; (*c*) a course of lectures on Midwifery and Diseases peculiar to Women during not less than three months; (*d*) systematic practical instruction in Medicine, Surgery, and Midwifery; (*e*) a course of lectures on Pathological Anatomy during not less than three months; (*f*) demonstrations in the post-mortem room during the whole period of attendance on clinical lectures; (*g*) a course of lectures on Forensic Medicine during not less than three months. 7 Of having attended, at a recognised hospital or hospitals, the practice of Medicine and Surgery during three winter and two summer sessions. 8. Of having attended at a recognised hospital or hospitals during nine months Clinical Lectures on Medicine, and during nine months Clinical Lectures on Surgery, and of having been engaged during a period of three months in the Clinical Study of Diseases peculiar to Women. 9. Of having discharged, after he has passed the Second Examination, the duties of a Medical Clinical Clerk during six months, and of a Surgical Dresser during other six months. 10. Of having received instruction in the practice of Vaccination.

Professional Examinations.—There are three Professional Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to the registrar of the Royal College of Physicians, or to the secretary of the Royal College of Surgeons, fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the First Examination are—Chemistry, Chemical Physics, Materia Medica, Pharmacy, Elementary Anatomy, and Elementary Physiology. A candidate may take this examination in three parts at different times, or he may present himself for the whole at one time. A candidate will be admitted to the examination on Chemistry and Chemical Physics, Materia Medica, and Pharmacy, on producing evidence of having been registered as a medical student by the General Medical Council, and of having received instruction in Chemistry, Materia Medica, and Pharmacy; but he will not be admitted to the examination on Elementary Anatomy and Elementary Physiology earlier than the end of his first winter session at a medical school. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected.

The fees for admission to the First Examination are as follows: for the whole examination, £10 10*s.*; for re-examination after rejection in either of the parts, £3 3*s.*

The subjects of the Second Examination are Anatomy and Physiology. A candidate may present himself for examination in either of these subjects or parts separately, or in both at one time. A candidate will be admitted to the Second Examination after the lapse of not less than six months from the date of his passing the First Examination, on producing evidence of having completed, subsequently to registration as a medical student, eighteen months of professional study at a recognised medical school or schools, and of having complied with the regulations prescribed in Section I., Clauses 4 and 5. A candidate rejected in either part or in both parts of the Second Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be re-examined in the subject or subjects in which he has been rejected.

The fees for admission to the Second Examination are as follows: for the whole examination, £10 10*s.*; for re-examination after rejection in either of the two parts, £3 3*s.*

The subjects of the Final Examination are: Medicine, including Therapeutics, Medical Anatomy, and Pathology; Surgery, including Surgical Anatomy and Pathology; Mid-

[24] Candidates can claim exemption from examination in Medicine and Midwifery under the following conditions—viz.: The production by the candidate of a degree, diploma, or licence in Medicine and Midwifery entitling him to register under the Medical Act of 1858, or a degree, diploma, or licence in Medicine and Midwifery of a colonial or foreign university approved by the Council of the College. A declaration by the candidate, prior to his admission to the Pass Examination, that it is his intention to obtain either of the qualifications in Medicine and Midwifery mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said qualification, or proof of having passed the several examinations entitling him to receive the same.

[25] This sum of £22 is exclusive of the fee of £2 paid for the Preliminary Examination.

Digitized by Google

wifery and Diseases peculiar to Women. A candidate may present himself for examination in these three subjects or parts separately or at one time. A candidate will be admitted to the Third or Final Examination on producing evidence:—(1) of being twenty-one years of age; (2) of having passed the second examination; and (3) of having studied Medicine, Surgery, and Midwifery, in accordance with the regulations prescribed in Section I., Clauses 2 and 6 to 10. The Colleges do not admit to either part of the Third or Final Examination any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least forty-five months, nor till the expiration of two years after his having passed the Second Examination. A candidate rejected in the Third or Final Examination, or in one or more of the three parts into which he may have divided it, will not be admitted to re-examination until after the lapse of a period of not less than six months from the date of rejection, and he will be re-examined in the subject or subjects in which he previously failed to pass. Any candidate who shall have obtained a colonial, Indian, or foreign qualification which entitles him to practise Medicine or Surgery in the country where such qualification has been conferred, after a course of study and examination equivalent to those required by the Regulations of the two Colleges, shall, on production of satisfactory evidence as to age and proficiency in Vaccination, be admissible to the Second and Third Examinations.

The fees for admission to the Third or Final Examination are as follows: for the whole examination, £15 15*s.*; for re-examination after rejection in Medicine, £5 5*s.*; for re-examination after rejection in Surgery, £5 5*s.*; for re-examination after rejection in Midwifery, £3 3*s.*

Notice.—A candidate referred at the Primary Examination in either or both subjects is required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his Teacher, or Teachers, in a recognised place of study, his Anatomical and Physiological Studies, or his Anatomical or Physiological Studies, as the case may be, during a period of not less than three months subsequently to the date of his reference.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

The above Colleges and Faculty have made arrangements by which, after one series of examinations, held in Edinburgh or in Glasgow, the student may obtain the diplomas of the three co-operating bodies. The general principle of this joint examination is that it shall be conducted by a board in which each body is represented in those branches which are common to both Medicine and Surgery, but that the College of Physicians shall take exclusive charge of the examination in Medicine, and the College of Surgeons, along with the Faculty of Physicians and Surgeons of Glasgow, of the examination in Surgery.

The three co-operating bodies grant their Single Qualifications only to candidates who are already registered as possessing another and opposite qualification in Medicine or Surgery, as the case may be. The Royal College of Physicians of Edinburgh may, notwithstanding this agreement, grant its licence on examination to candidates already possessed of one or other of the surgical qualifications mentioned in Schedule A of the Medical Act, 1858; and the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, may each grant its licence on examination to candidates already Licentiates of one of the Colleges of Physicians of the United Kingdom, or Graduates in Medicine of a British or Irish University. Copies of the Regulations for the Single Qualification of any of the bodies may be had on application to the respective secretaries.

Professional Education.—Candidates must have been engaged in professional study during forty-five months after passing the examination in General Education,[28] which period will include not less than four winter sessions or three winter and two summer sessions' attendance at a recognised medical school. At the meeting of the General Medical Council in May, 1886, it was recommended that hereafter the duration of study should be five years.

The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of lectures: Anatomy, Practical Anatomy, Chemistry, Practical or Analytical Chemistry, Materia Medica, Physiology, Practice of Medicine, Clinical Medicine, Principles and Practice of Surgery, Clinical Surgery, Midwifery and the Diseases of Women and Children, Medical Jurisprudence, Pathological Anatomy. The six months' courses delivered in Scotland, with the exception of Clinical Medicine and Clinical Surgery, must consist of not fewer than 100 lectures. The three months' courses must consist of not fewer than 50 lectures. The candidate must also produce the following certificates: (*a*) Of having attended six cases of labour under the superintendence of the practitioner who signs the certificate, who must be a registered medical practitioner. (*b*) Of having attended for three months instruction in Practical Pharmacy, the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy. (*c*) Of having attended for twenty-four months the practice of a public general hospital containing, on an average, at least eighty patients. (*d*) Of having attended for six months (or three months with three months' hospital clerkship) the practice of a public dispensary specially recognised by any of the co-operating bodies; or of having been engaged for six months as visiting assistant to a registered practitioner. (*e*) Of having been instructed by a registered medical practitioner in the Theory and Practice of Vaccination. Candidates shall be subjected to three Professional Examinations, herein called the First Examination, the Second Examination, and the Final Examination, to be conducted at separate times, partly in writing and partly practically and orally.

The First Examination will embrace Chemistry, Practical Chemistry, Elementary Anatomy, and Histology, and will take place not sooner than the end of the first year, including a winter and a summer session. The sum of £5 5*s.* must be paid to the Inspector of Certificates for this examination, not later than 11 A.M. of the Saturday preceding it. This sum will be considered as paid to account of the entire fee of £26 5*s.* payable for the three diplomas. In the case of a candidate being unsuccessful at this examination, he will be readmitted to examination after a prescribed interval on payment of £3 3*s.* if he has failed in all subjects, and £2 2*s.* if he has passed in one or more subjects. Any candidate who shall produce satisfactory evidence of having passed an examination in any of the subjects of the First Examination before any of the boards recognised by the co-operating authorities shall be exempt from examination in such subject or subjects. The certificates of examination upon which any candidate may claim exception from any of the subjects of the First and Second Examinations shall, in every case, specify the subjects embraced in such examination.

The Second Examination will embrace Anatomy, Physiology, Materia Medica, and Pharmacy, and will not take place before the termination of the summer session of the second year of study, including two winter and two summer sessions. The sum of £5 5*s.* must be paid to the Inspector of Certificates for this examination, not later than one week before the day of examination. In case of failure, the candidate will be readmitted to examination after the expiration of the prescribed period on payment of £3 3*s.* if he has failed in all subjects, and £2 2*s.* if he has passed in one or more subjects. Any candidate who shall produce satisfactory evidence of having passed in any of the subjects of the Second Examination before any of the boards recognised by the co-operating authorities will be exempt from examination in such subject or subjects; but no examination before such boards will be recognised as giving exemption unless it is co-extensive in its scope with the equivalent examination of this board, and is the only or the final examination on the subject or subjects required by the board at which it was passed.

The Final Examination will embrace the Principles and Practice of Medicine (including Therapeutics, Medical Anatomy and Pathology), Clinical Medicine, the Principles and Practice of Surgery (including Surgical Aatomy, Operative Surgery, and Surgical Pathology), Clinical Surgery, Midwifery (including Gynæcology), Medical Jurisprudence, and Hygiene, and it will not take place before the termination of the full period of study. Candidates shall not be exempted from examination in any of the subjects of the Final Examination, though some of them may have formed part of examinations passed before other boards.

[28] See the Laws relating to Registration.

Digitized by Google

All candidates shall be subjected, in addition to the written and oral examinations, to practical clinical examinations in medicine and surgery, which shall include the examination of patients, physical diagnosis, the use of the microscope, surgical appliances, bandages, &c. Every candidate must produce to the inspector, Mr. James Robertson, solicitor, 4, Lindsay-place (George IV. Bridge), Edinburgh, or to Mr. Alexander Duncan, Faculty Hall, 242, St. Vincent-street, Glasgow—(1) satisfactory evidence of his having attained the age of twenty-one years; (2) a certificate of his registration in the books of the General Medical Council (see Chap. IV.); (3) the certificates of the classes above enumerated. Of the fee payable for this examination, which is £15 15*s*., £5 5*s*. must be paid to the inspector not later than one week prior to the examination day, after which no candidate will be entered. The balance of £10 10*s*. must be paid before the candidate is admitted a licentiate of the co-operating bodies. In case of a candidate being unsuccessful at the Final Examination, he will be re-admitted to examination after the expiration of the prescribed period on payment of £5 5*s*.

KING AND QUEEN'S COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

All information relative to the examinations under the Joint Scheme may be obtained from the Registrars of the College of Physicians and College of Surgeons, either of whom will receive the applications of candidates for permission to be examined, and with whom the bank receipt for fees and all certificates &c. are to be lodged at least fourteen days prior to the day fixed for the commencement of the examination.

The examinations commence on the first Monday in April, July, and October of each year, unless otherwise appointed by the Committee of Management.

First Professional Examination.—Candidates are required, before admission to the First Professional Examination, to produce evidence—(1) of having been registered by the General Medical Council as medical students at least nine months before the date of examination; (2) of having attended a course of lectures on Practical Anatomy, and one on Chemistry; (3) of having attended a course of Demonstrations and Dissections; (4) of having attended a summer course on Materia Medica, and one on Practical Chemistry; (5) of having studied Practical Pharmacy for three months in the Compounding Department of a Clinical Hospital, or in the Compounding Establishment of a Licentiate Apothecary or Member of the Pharmaceutical Society. The fee for this examination is £15 15*s*.

Second Profesional Examination.—Candidates are required, before admission to the Second Professional Examination, to produce evidence of having passed the First Professional Examination; also certificates of having subsequently attended a Medico-Chirurgical Hospital for nine months, together with evidence of having taken notes to the satisfaction of the physicians or surgeons in charge of the cases, and certified under their hands of at least three Medical cases and three Surgical cases, in the wards of a recognised Medico-Chirurgical Hospital, and the following courses of Lectures:—Winter courses: Practical Anatomy, Demonstrations and Dissections, Physiology, Surgery. Summer course, three months: Practical Physiology, including Histology. The fee for this examination is £5 5*s*.

Third Professional Examination.—Candidates are required, before admission to the Third Professional Examination, to produce evidence of having passed the second examination; also certificates of having subsequently attended a Medico-Chirurgical Hospital for nine months, together with evidence of having taken notes to the satisfaction of the Physicians and Surgeons in charge of the cases, and certified under their hands, of at least three Medical cases, and three Surgical cases in the wards of a recognised Medico-Chirurgical Hospital, and of the following courses of Lectures:—Winter courses: Demonstrations and Dissections, Medicine, Midwifery, if not deferred to the fourth year. Summer course, three months: Medical Jurisprudence. The fee for this examination is £5 5*s*.

Fourth or Final Professional Examination.—Candidates are required, before admission to the Final Examination, to produce evidence—(1) of having been registered as a medical student by the General Medical Council at least forty-five months previously; (2) of having passed the Third Professional Examination; (3) of having subsequently attended a Medico-Chirurgical Hospital for nine months as extern pupil, or six months as resident pupil, unless a certificate to that effect has been accepted in the third year, and of having attended the following course of lectures:—Winter Course: Midwifery, unless taken in the third year. Certificates are also required—(1) of having attended a recognised midwifery hospital or maternity for six months in the winter or summer of either the third or the fourth year, with evidence of having been present at thirty labours; (2) of having for not less than three months studied fever in a recognised clinical hospital containing fever wards, and recorded from daily personal observation at least five cases of fever to the satisfaction of the attending clinical physician, as attested by his signature;[27] (3) of having attended a course of Operative Surgery in the summer session of either the third or fourth year; (4) of having attended, at a recognised ophthalmic and aural hospital, or at a recognised ophthalmic and aural department of a general hospital, clinical lectures in Ophthalmic and Aural Surgery during a period of three months. The fee for this examination is £15 15*s*.

SOCIETY OF APOTHECARIES OF LONDON.

Every student purposing to study medicine must previously pass a public examination in Arts recognised by the Medical Council. Such examination is held in the Hall of the Society on the first Friday and following day in March, June, September, and December, and is conducted by means of printed papers. Candidates will be examined in the English and Latin languages, Mathematics, Elementary Mechanics, and one of the following subjects at the option of the candidate—Greek, French, German, Logic, Botany, and Elementary Chemistry. The subjects may be passed at one or more examinations, and no re-examination is required in any subject passed. Registered medical students may present themselves for examination in special subjects if desired. A form of notice accompanying the regulations, obtained from the Society, has to be filled in by the candidate and sent with the fee (one guinea) fourteen days before the examination. Lists of successful candidates are published.

The examinations to be passed for the licence are two, named respectively the Primary and the Final, each being written, oral, and practical. The Primary is held on the first Monday and following Wednesday and Thursday in January, April, July, and October. The Final is divided into two parts: Part I. (Surgery) is held on the second and fourth Wednesday and following day of every month; Part II. (Medicine) is held on the third Monday and following Wednesday and Thursday of every month. The course of medical study must occupy four years, of which not less than three winter and two summer sessions must be passed at a recognised hospital and school of medicine.

Every candidate intending to present himself for examination must pay a fee of 10 guineas, of which sum 4 guineas are to be paid at the Primary. He must also give fourteen days' notice, and produce the following certificates: (1) for the Primary Examination, a certificate of the commencement of attendance on lectures, and of the course of medical study pursued; (2) for the Final Examination, a certificate of having completed four years' medical study in conformity with the curriculum prescribed, of moral character, and of having attained the age of twenty-one. On such certificates being found correct, a card of admission to the examination will be sent, stating the time of attendance.

Every candidate, before he can be qualified for the Primary Examination, must have gone through a course of medical study in Chemistry, General and Practical; Materia Medica; Pharmacy and Dispensing; Anatomy and Physiology, including Dissections and Demonstrations; and Histology, with Demonstrations. The above, including Prescriptions, Practical Chemistry in the Laboratory, and an examination on the living body, form the several subjects of examination for the Primary, which examination may be passed after the second winter session.

For the Final Examination the candidate must give evidence, before he can present himself, that he has gone through the following course of medical study:—Hospital Practice, Surgical and Medical, with Post-mortem Examinations; Principles and Practice of Surgery; Practical Sur-

[27] Attendance at a fever hospital will not be recognised if concurrent with that on Practical Midwifery.

Digitized by Google

gery; Clinical Surgical Lectures; Surgical Dresser; Principles and Practice of Medicine; Clinical Medical Lectures; Medical Clinical Clerk; Pathology; Forensic Medicine and Toxicology: Hygiene; Insanity; Obstetric Medicine and Gynæcology; Clinical Instruction in the same; a course of Practical Midwifery; attendance on not less than twenty Midwifery cases; and Practical Vaccination.

The Final Examination, which cannot be passed till after the completion of the medical course and the expiration of forty-five months from registration as medical student, embraces the above; and, in addition, in Part I., Surgical Anatomy, Surgical Pathology, surgical instruments and appliances, with a clinical examination of surgical cases; in Part II., obstetric instruments and appliances, microscopic examinations of morbid structure, and a clinical examination of medical cases. Part II. may be passed before Part I. if desired.

The Society give annually prizes for proficiency in Botany, in Materia Medica, and in Pharmaceutical Chemistry to registered medical students prior to the close of the third year, who have not been candidates for the prizes previously. They must reach the required standard. The examination in Botany is held on the third Thursday and following Saturday in June. That in Materia Medica and Pharmaceutical Chemistry is held on the third Wednesday and following day in August. The prizes for each consist of a Gold Medal, to be awarded to the candidate who distinguishes himself the most in the examination; and of a Silver Medal and a Book, or Books, to the candidate who does so in the next degree.

The examination of candidates for a certificate to act as an assistant in compounding and dispensing medicines, will be as follows:—In Translating Prescriptions; in the British Pharmacopœia; in Pharmacy, Pharmaceutical Chemistry, Materia Medica, and Medical Botany. Such examination is held on the third Thursday of every month: seven days' notice must be given, and a fee of 2 guineas paid.

Tickets of admission to the Society's Botanic Gardens at Chelsea, and to the Lectures on Botany when there given, can be had on application at the Hall of the Society.

APOTHECARIES' HALL OF IRELAND.

The Apothecaries' Hall of Ireland is at present engaged in completing a conjoint scheme of examination with the Royal College of Surgeons of Ireland, which, it is hoped, will be concluded by the end of this month. Till then particulars of the scheme cannot be published.

THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

Admission into the Army and Indian Medical Services is gained as the result of competitive examination. Candidates for both services must, before being admitted to examination, possess the double qualification to practise Medicine and Surgery, and be registered under the Medical Act, and must also furnish satisfactory certificates of moral character. Candidates for the Army must be between the ages of twenty-one and twenty-eight, in good health, and both parents of unmixed European blood; for the Indian Service, between twenty-two and twenty-eight, of sound bodily health, and natural-born subjects of Her Majesty. Both are examined as to physical fitness by a Board of Medical Officers. These conditions being satisfied, the candidate is admitted to the competitive examination, which is usually held in London twice a year, in the months of February and August. The subjects of examination are divided into *compulsory* and *voluntary*. The former comprise Anatomy and Physiology, Surgery, Medicine, including Therapeutics and the Diseases of Women and Children, Chemistry and Pharmacy, and a practical knowledge of Drugs. The eligibility of the candidate for admission into the service is determined by the result of this part of the examination. The *voluntary* subjects are French, German, Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany, with especial reference to Materia Medica, and for the Indian service Hindustani. Although the results of the examination on voluntary subjects do not affect the question of the eligibility of the candidate for a commission, they influence his position on the lists, which is determined by the numbers obtained under the two heads conjointly. After having passed this examination, the successful candidates for both services are sent to the Army Medical School at Netley as "surgeons on probation," with the rank of lieutenant and the daily pay of 8*s.*, to go through a four months' course of special instruction in the duties required of them in the service. The staff of the school consists of four professors, all of them men of acknowledged ability and high standing in their special departments. Surgeon-General Sir J. Longmore, Kt., C.B., is Professor of Military Surgery; Deputy Surgeon-General D. B. Smith, M.D., of Military Medicine; Surgeon-Major De Chaumont, M.D., F.R.S., of Military Hygiene; and Sir W. Aitken, F.R.S., of Pathology. To each of these an Army Medical Officer is attached as Assistant Professor. The lectures on Military Surgery include gunshot and other wounds, transport of sick and wounded, duties of army medical officers in the field, during sieges, and on board troopships and transports, &c. Those on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad. The course of Hygiene comprises the examination of water and air, the general principles of diet, with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the clothing, duties, and exercises of the soldier, and the circumstances affecting his health with the best means of preventing disease, and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The surgeons on probation are detailed for duty in the wards of the hospital, under the Professors and Assistant Professors of Medicine and Surgery, and receive practical instruction in the mode of examining recruits. The surgeons on probation are provided with quarters, and are members of the excellent mess established at Netley. After having passed through the course of instruction they are examined on the subjects taught in the school, and their position on the list recommended for commissions is determined by the combined results of the competitive and final examinations. At the close of each session five prizes are awarded: the Herbert Prize of £20 to the surgeon on probation who has obtained the highest number of marks at the London and Netley examinations conjointly; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination on Hygiene at Netley, combined with those given for the answers to a special question set on the same subject; the Martin Memorial Gold Medal to the highest number of marks in the final examination on Military Medicine, with the addition of those gained for a special question connected with it; the Montefiore Gold Medal and £20, awarded in the same manner for Military Surgery; and the Montefiore Second Prize, consisting of works on Military Surgery, to the surgeon on probation who obtains the second highest numbers in this branch.

Surgeons are promoted to be Surgeons-Major on completing twelve years' full-pay service, of which three must have been abroad. Before being promoted they will be required to pass an examination intended to test their progress and proficiency in all those branches of knowledge which are essential to their continued efficiency as medical officers, which may be taken at any time between the fifth and tenth year of service. It will embrace the following subjects: *a.* Surgery, operative and practical, including field surgery and transport of sick and wounded. *b.* Medicine and Pathology, including practical pharmacy and modes of prescribing and administering remedial measures, food, drink, &c. *c.* Hygiene, within the limits treated of in "Parkes' Practical Hygiene." *d.* Duties of executive medical officers during peace and war at home and abroad, and at sea, as defined in the various codes of regulations issued for their guidance. Medical officers possessing the following qualifications will be exempted from examination in Medicine, Surgery, and Hygiene respectively: *a.* The Fellowship of any Royal College of Physicians or Surgeons of Great Britain or Ireland, granted under a higher standard of qualification than that for Licentiate or Member, will be accepted in lieu of an examination in Medicine and Surgery. *b.* The diploma in Hygiene and State Medicine, or any corresponding diploma of any University in Great Britain or Ireland, such diploma being granted after examination, will be accepted in lieu of an examination in this subject. A certificate will be required from a recognised teacher of Surgery in any medical school at home or abroad in which operative surgery is taught, showing that the medical officer has gone satisfac-

Digitized by Google

torily through a complete course of operative surgery during the period within which the examination must be taken, and that he is a competent operator. A report on any subject of a practical professional character to be selected by the officer himself, and certified to be his own composition, and in his own handwriting, will also be required.

The selection of Surgeons-Major for advancement to the grade of Brigade Surgeon is made on the grounds of ability and merit, in determining which the following points will be considered:—The officer to be so selected must have been favourably reported on by the several military and departmental officers under whom he may have served, as set forth in their Annual Confidential Reports. He must be physically fit for general service, and have the necessary qualifying foreign and Indian service under existing rules. He must, before he can be selected for promotion to the grade of Brigade Surgeon, establish before an examining board, appointed for the purpose by the Director-General, his efficiency in the following subjects:—*a.* Hospital organisation and administration in peace and war. *b.* The administration, interior economy, command, and discipline of the Medical Staff Corps and bearer columns. *c.* The relations of the medical to all other departments and corps of the army, as defined by the various Codes of Regulations in force. *d.* Recruiting and invaliding. *e.* The management of sick and wounded in war. *f.* Field medical organisation. *g.* The transport of the sick and wounded by land and sea. *h.* The medical and surgical equipment and hospital arrangements for an army corps. *i.* The duties and responsibilities of medical officers, quartermasters, and non-commissioned officers and men of the Medical Staff Corps in regard to the charge and supervision of stores and equipments, and the nursing, dieting, and general management of the sick. *k.* The sanitary duties of medical officers in charge of camps and hospitals in the field and at the base of operations. *l.* The sanitary inspection and equipment of hospital ships and troop transports, and all other sanitary duties in camps, garrisons, and quarters. *m.* The origin, progress, and best methods of dealing with outbreaks of epidemic disease among troops under any given circumstance. *n.* The most approved methods of securing the sick, and especially the wounded, against pyæmia, septicæmia, and all other forms of blood poisoning, and the management and treatment of such outbreaks when they occur. *o.* Questions on Operative Surgery and Practical Medicine will also form part of this examination. A medico-topographical report will be required of any district or country in which British troops have been, or are likely to be, actively employed, as well as a sketch of the medical arrangements suitable for an army corps operating in such a district or country, compiled by the officer, and certified to be his own composition and in his own handwriting.

Brigade Surgeons, to be eligible for selection as Deputy Surgeons-General, must have served abroad at least ten years, of which three must have been in India. All officers under the rank of Deputy Surgeon-General are placed on the retired list at the age of fifty-five, and those of that rank and Surgeons-General at the age of sixty.

The regulations above noted respecting the promotion of Surgeons and Surgeons-Major are equally applicable to the Indian Medical Service.

The conditions of admission into the Naval Medical Service are the same as those for the Army; but the candidate is also required to declare his readiness to engage for general service, and to proceed on duty abroad whenever required to do so. After having passed the competitive examination in London the successful candidate will receive a commission as surgeon in the Royal Navy, "and will undergo a course of practical instruction in Naval Hygiene at Haslar Hospital."

Surgeons are promoted to Staff Surgeons after twelve years from date of entry, provided they pass the requisite examination; and Staff Surgeons to Fleet Surgeons after twenty years' service, if recommended by the Director-General. Deputy Inspectors-General are promoted by selection from the Fleet Surgeons, and Inspectors-General from the Deputy Inspectors-General having three years' foreign, four years' mixed, of which not less than two have been abroad, or five years' home service in such appointments as preclude foreign service, provided they have not refused to go abroad when called upon to do so. Inspectors and Deputy Inspectors-General are retired compulsorily at sixty, and other grades at fifty-five years of age, and all ranks at any time if they have not served for five years. In calculating service for retired pay, time on half-pay will be taken as equivalent to one-third service on full-pay.

The following tables, showing the rates of pay and half-pay of the three branches, will probably be acceptable to students who entertain any intention of entering the public service.
